Today's Biz

1. **Reminders**
2. Review
3. Random Networks
4. Random network generation and comparisons

Reminders

- ▶ Project Presentation 1: in class 6 October
 - ▶ Email me your slides (pdf only please) before class
 - ▶ 5-10 minute presentation
 - ▶ Introduce topic, give background, current progress, expected results
- ▶ **No class 10/11 October**
- ▶ Assignment 3: Thursday 13 Oct 16:00
- ▶ Office hours: Tuesday & Wednesday 14:00-16:00 Lally 317
 - ▶ **No office hours 11-12 Oct, available via email**
 - ▶ Or email me for other availability

Today's Biz

1. Reminders
2. **Review**
3. Random Networks
4. Random network generation and comparisons

Quick Review

- ▶ Network motifs
 - ▶ Small recurring patterns (subgraphs) that may serve important function
 - ▶ Functional context is network-dependent
 - ▶ Motif: occurs more frequently than expected vs. random networks
 - ▶ Anti-motif: less frequent, possible anomaly
- ▶ Graph alignment
 - ▶ Identify regions of high similarity between networks
 - ▶ “Approximate subgraph isomorphism” - allow edge/node deletions/additions
- ▶ Weighted path finding
 - ▶ Detecting signaling pathways - interaction pathways of high probability

Today's Biz

1. Reminders
2. Review
3. **Random Networks**
4. Random network generation and comparisons

Random Networks

Slides from Maarten van Steen, VU Amsterdam

Introduction

Observation

Many real-world networks can be **modeled** as a random graph in which an edge $\langle u, v \rangle$ appears with probability p .

Spatial systems: Railway networks, airline networks, computer networks, have the property that the closer x and y are, the higher the probability that they are linked.

Food webs: Who eats whom? Turns out that techniques from random networks are useful for getting insight in their structure.

Collaboration networks: Who cites whom? Again, techniques from random networks allows us to understand what is going on.

Erdős-Rényi graphs

Erdős-Rényi model

An undirected graph $ER(n, p)$ with n vertices. Edge $\langle u, v \rangle$ ($u \neq v$) exists with probability p .

Note

There is also an alternative definition, which we'll skip.

ER-graphs

Notation

$\mathbb{P}[\delta(u) = k]$ is probability that degree of u is equal to k .

- There are maximally $n - 1$ other vertices that can be adjacent to u .
- We can choose k other vertices, out of $n - 1$, to join with u
 $\Rightarrow \binom{n-1}{k} = \frac{(n-1)!}{(n-1-k)! \cdot k!}$ possibilities.
- Probability of having exactly one specific set of k neighbors is:

$$p^k(1-p)^{n-1-k}$$

Conclusion

$$\mathbb{P}[\delta(u) = k] = \binom{n-1}{k} p^k (1-p)^{n-1-k}$$

ER-graphs: average vertex degree (the simple way)

Observations

- We know that $\sum_{v \in V(G)} \delta(v) = 2 \cdot |E(G)|$
- We also know that between each two vertices, there exists an edge with probability p .
- There are at most $\binom{n}{2}$ edges
- **Conclusion:** we can expect a total of $p \cdot \binom{n}{2}$ edges.

Conclusion

$$\bar{\delta}(v) = \frac{1}{n} \sum \delta(v) = \frac{1}{n} \cdot 2 \cdot p \binom{n}{2} = \frac{2 \cdot p \cdot n \cdot (n-1)}{n \cdot 2} = p \cdot (n-1)$$

Even simpler

Each vertex can have maximally $n-1$ incident edges \Rightarrow we can expect it to have $p(n-1)$ edges.

ER-graphs: average vertex degree (the hard way)

Observation

All vertices have the same probability of having degree k , meaning that we can treat the degree distribution as a **stochastic variable** δ . We now know that δ follows a binomial distribution.

Recall

Computing the average (or **expected value**) of a stochastic variable x , is computing:

$$\bar{x} \stackrel{\text{def}}{=} \mathbb{E}[x] \stackrel{\text{def}}{=} \sum_k k \cdot \mathbb{P}[x = k]$$

ER-graphs: average vertex degree (the hard way)

$$\begin{aligned}
 \sum_{k=1}^{n-1} k \cdot \mathbb{P}[\delta = k] &= \sum_{k=1}^{n-1} \binom{n-1}{k} k p^k (1-p)^{n-1-k} \\
 &= \sum_{k=1}^{n-1} \binom{n-1}{k} k p^k (1-p)^{n-1-k} \\
 &= \sum_{k=1}^{n-1} \frac{(n-1)!}{k!(n-1-k)!} k p^k (1-p)^{n-1-k} \\
 &= \sum_{k=1}^{n-1} \frac{(n-1)(n-2)!}{k(k-1)!(n-1-k)!} k p \cdot p^{k-1} (1-p)^{n-1-k} \\
 &= \sum_{k=1}^{n-1} \frac{(n-1)(n-2)!}{k(k-1)!(n-1-k)!} k p \cdot p^{k-1} (1-p)^{n-1-k} \\
 &= p(n-1) \sum_{k=1}^{n-1} \frac{(n-2)!}{(k-1)!(n-1-k)!} p^{k-1} (1-p)^{n-1-k}
 \end{aligned}$$

ER-graphs: average vertex degree (the hard way)

$$\sum_{k=1}^{n-1} k \cdot \mathbb{P}[\delta = k] = p(n-1) \sum_{k=1}^{n-1} \frac{(n-2)!}{(k-1)!(n-1-k)!} p^{k-1} (1-p)^{n-1-k}$$

$$\{\text{Take } l \equiv k-1\} = p(n-1) \sum_{l=0}^{n-2} \frac{(n-2)!}{l!(n-1-(l+1))!} p^l (1-p)^{n-1-(l+1)}$$

$$= p(n-1) \sum_{l=0}^{n-2} \frac{(n-2)!}{l!(n-2-l)!} p^l (1-p)^{n-2-l}$$

$$= p(n-1) \sum_{l=0}^{n-2} \binom{n-2}{l} p^l (1-p)^{n-2-l}$$

$$\{\text{Take } m \equiv n-2\} = p(n-1) \sum_{l=0}^m \binom{m}{l} p^l (1-p)^{m-l}$$

$$= p(n-1) \cdot 1$$

Examples of ER-graphs

Important

$ER(n, p)$ represents a **group** of Erdős-Rényi graphs: most $ER(n, p)$ graphs are **not isomorphic**!

$$G \in ER(100, 0.3)$$

$$G^* \in ER(2000, 0.015)$$

Examples of ER-graphs

Some observations

- $G \in ER(100, 0.3) \Rightarrow$
 - $\bar{\delta} = 0.3 \times 99 = 29.7$
 - Expected $|E(G)| = \frac{1}{2} \cdot \sum \delta(v) = np(n-1)/2 = \frac{1}{2} \times 100 \times 0.3 \times 99 = 1485.$
 - In our example: 490 edges.
- $G^* \in ER(2000, 0.015) \Rightarrow$
 - $\bar{\delta} = 0.015 \times 1999 = 29.985$
 - Expected $|E(G)| = \frac{1}{2} \sum \delta(v) = np(n-1)/2 = \frac{1}{2} \times 2000 \times 0.015 \times 1999 = 29,985.$
 - In our example: 29,708 edges.
- The larger the graph, the more probable its degree distribution will follow the expected one (**Note**: not easy to show!)

ER-graphs: average path length

Observation

For any large $H \in ER(n, p)$ it can be shown that the average path length $\bar{d}(H)$ is equal to:

$$\bar{d}(H) = \frac{\ln(n) - \gamma}{\ln(pn)} + 0.5$$

with γ the Euler constant (≈ 0.5772).

Observation

With $\bar{\delta} = p(n-1)$, we have

$$\bar{d}(H) \approx \frac{\ln(n) - \gamma}{\ln(\bar{\delta})} + 0.5$$

ER-graphs: average path length

Example: Keep average vertex degree fixed, but change size of graphs:

ER-graphs: average path length

Example: Keep size fixed, but change average vertex degree:

ER-graphs: clustering coefficient

Reasoning

- Clustering coefficient: fraction of edges between neighbors and maximum possible edges.
- Expected number of edges between k neighbors: $\binom{k}{2}p$
- Maximum number of edges between k neighbors: $\binom{k}{2}$
- Expected clustering coefficient for every vertex: p

ER-graphs: connectivity

Giant component

Observation: When increasing p , most vertices are contained in the same component.

ER-graphs: connectivity

Robustness

Experiment: How many vertices do we need to remove to partition an ER-graph? Let $G \in ER(2000, 0.015)$.

Small worlds: Six degrees of separation

Stanley Milgram

- Pick two people at random
- Try to measure their distance: A knows B knows C ...
- **Experiment:** Let Alice try to get a letter to Zach, whom she does not know.
- **Strategy by Alice:** choose Bob who she thinks has a better chance of reaching Zach.
- **Result:** On average 5.5 hops before letter reaches target.

Small-world networks

General observation

Many real-world networks show a small average shortest path length.

Observation

ER-graphs have a small average shortest path length, but not the high clustering coefficient that we observe in real-world networks.

Question

Can we construct **more realistic models** of real-world networks?

Watts-Strogatz graphs

Algorithm (Watts-Strogatz)

$V = \{v_1, v_2, \dots, v_n\}$. Let k be even. Choose $n \gg k \gg \ln(n) \gg 1$.

- 1 Order the n vertices into a ring
- 2 Connect each vertex to its first $k/2$ right-hand (counterclockwise) neighbors, and to its $k/2$ left-hand (clockwise) neighbors.
- 3 With probability p , replace edge $\langle u, v \rangle$ with an edge $\langle u, w \rangle$ where $w \neq u$ is randomly chosen, but such that $\langle u, w \rangle \notin E(G)$.
- 4 **Notation:** $WS(n, k, p)$ graph

Watts-Strogatz graphs

$p = 0.0$

$p = 0.20$

$p = 0.90$

Note

$n = 20$; $k = 8$; $\ln(n) \approx 3$. Conditions are not really met.

Watts-Strogatz graphs

Observation

For many vertices in a WS-graph, $d(u, v)$ will be small:

- Each vertex has k nearby neighbors.
- There will be direct links to other “groups” of vertices.
- **weak links**: the **long** links in a WS-graph that cross the ring.

WS-graphs: clustering coefficient

Theorem

For any G from $WS(n, k, 0)$, $CC(G) = \frac{3}{4} \frac{k-2}{k-1}$.

Proof

Choose arbitrary $u \in V(G)$. Let $H = G[N(u)]$. Note that $G[\{u\} \cup N(u)]$ is equal to:

WS-graphs: clustering coefficient

Proof (cntd)

- $\delta(v_1^-)$: The “farthest” right-hand neighbor of v_1^- is $v_{k/2}^-$
- Conclusion: v_1^- has $\frac{k}{2} - 1$ right-hand neighbors in H .
- v_2^- has $\frac{k}{2} - 2$ right-hand neighbors in H .
- In general: v_i^- has $\frac{k}{2} - i$ right-hand neighbors in H .

WS-graphs: clustering coefficient

Proof (cntd)

- v_i^- is missing only u as left-hand neighbor in $H \Rightarrow v_i^-$ has $\frac{k}{2} - 1$ left-hand neighbors.
- $\delta(v_i^-) = \left(\frac{k}{2} - 1\right) + \left(\frac{k}{2} - i\right) = k - i - 1$ [Same for $\delta(v_i^+)$]

WS-graphs: clustering coefficient

Proof (cntd)

- $|E(H)| = \frac{1}{2} \sum_{v \in V(H)} \delta(v) =$
 $\frac{1}{2} \sum_{i=1}^{k/2} \left(\delta(v_i^-) + \delta(v_i^+) \right) = \frac{1}{2} \cdot 2 \sum_{i=1}^{k/2} \delta(v_i^-) = \sum_{i=1}^{k/2} (k-i-1)$
- $\sum_{i=1}^m i = \frac{1}{2} m(m+1) \Rightarrow |E(H)| = \frac{3}{8} k(k-2)$
- $|V(H)| = k \Rightarrow$

$$cc(u) = \frac{|E(H)|}{\binom{k}{2}} = \frac{\frac{3}{8} k(k-2)}{\frac{1}{2} k(k-1)} = \frac{3(k-2)}{4(k-1)}$$

WS-graphs: average shortest path length

Theorem

$\forall G \in WS(n, k, 0)$ the average shortest-path length $\bar{d}(u)$ from vertex u to any other vertex is approximated by

$$\bar{d}(u) \approx \frac{(n-1)(n+k-1)}{2kn}$$

WS-graphs: average shortest path length

Proof

- Let $L(u, 1) =$ left-hand vertices $\{v_1^+, v_2^+, \dots, v_{k/2}^+\}$
- Let $L(u, 2) =$ left-hand vertices $\{v_{k/2+1}^+, \dots, v_k^+\}$.
- Let $L(u, m) =$ left-hand vertices $\{v_{(m-1)k/2+1}^+, \dots, v_{mk/2}^+\}$.
- Note: $\forall v \in L(u, m) : v$ is connected to a vertex from $L(u, m-1)$.

Note

$L(u, m) =$ left-hand neighbors connected to u through a (shortest) path of length m . Define analogously $R(u, m)$.

WS-graphs: average shortest path length

Proof (cntd)

- Index p of the farthest vertex v_p^+ contained in any $L(u, m)$ will be less than approximately $(n-1)/2$.
- All $L(u, m)$ have equal size $\Rightarrow m \cdot k/2 \leq (n-1)/2 \Rightarrow m \leq \frac{(n-1)/2}{k/2}$.

$$\bar{d}(u) \approx 2 \frac{1 \cdot |L(u,1)| + 2 \cdot |L(u,2)| + \dots + \frac{n-1}{k} \cdot |L(u,m)|}{n}$$

which leads to

$$\bar{d}(u) \approx \frac{k}{n} \sum_{i=1}^{(n-1)/k} i = \frac{k}{2n} \left(\frac{n-1}{k} \right) \left(\frac{n-1}{k} + 1 \right) = \frac{(n-1)(n+k-1)}{2kn}$$

WS-graphs: comparison to real-world networks

Observation

$WS(n, k, 0)$ graphs have long shortest paths, yet high clustering coefficient. However, increasing p shows that average path length drops rapidly.

Normalized: divide by $CC(G_0)$
and $\bar{d}(G_0)$ with
 $G_0 \in WS(n, k, 0)$

Scale-free networks

Important observation

In many real-world networks we see very few high-degree nodes, and that the number of high-degree nodes decreases exponentially: Web link structure, Internet topology, collaboration networks, etc.

Characterization

In a scale-free network, $\mathbb{P}[\delta(u) = k] \propto k^{-\alpha}$

Definition

A function f is **scale-free** iff $f(bx) = C(b) \cdot f(x)$ where $C(b)$ is a constant dependent only on b

Example scale-free network

What's in a name: scale-free

Constructing SF networks

Observation

Where ER and WS graphs can be constructed from a given set of vertices, scale-free networks result from a **growth process** combined with **preferential attachment**.

Barabási-Albert networks

Algorithm (Barabási-Albert)

$G_0 \in ER(n_0, p)$ with $V_0 = V(G_0)$. At each step $s > 0$:

- 1 Add a new vertex v_s : $V_s \leftarrow V_{s-1} \cup \{v_s\}$.
- 2 Add $m \leq n_0$ edges incident to v_s and a vertex u from V_{s-1} (and u not chosen before in current step). Choose u with probability

$$\mathbb{P}[\text{select } u] = \frac{\delta(u)}{\sum_{w \in V_{s-1}} \delta(w)}$$

Note: choose u proportional to its current degree.

- 3 Stop when n vertices have been added, otherwise repeat the previous two steps.

Result: a **Barabási-Albert graph**, $BA(n, n_0, m)$.

BA-graphs: degree distribution

Theorem

For any $BA(n, n_0, m)$ graph G and $u \in V(G)$:

$$\mathbb{P}[\delta(u) = k] = \frac{2m(m+1)}{k(k+1)(k+2)} \propto \frac{1}{k^3}$$

Generalized BA-graphs

Algorithm

G_0 has n_0 vertices V_0 and no edges. At each step $s > 0$:

- 1 Add a new vertex v_s to V_{s-1} .
- 2 Add $m \leq n_0$ edges incident to v_s and different vertices u from V_{s-1} (u not chosen before during current step). Choose u with probability proportional to its current degree $\delta(u)$.
- 3 For some constant $c \geq 0$ add another $c \times m$ edges between vertices from V_{s-1} ; probability adding edge between u and w is proportional to the product $\delta(u) \cdot \delta(w)$ (and $\langle u, w \rangle$ does not yet exist).
- 4 Stop when n vertices have been added.

Generalized BA-graphs: degree distribution

Theorem

For any generalized $BA(n, n_0, m)$ graph G and $u \in V(G)$:

$$\mathbb{P}[\delta(u) = k] \propto k^{-(2 + \frac{1}{1+2c})}$$

Observation

- For $c = 0$, we have a BA-graph;
- $\lim_{c \rightarrow \infty} \mathbb{P}[\delta(u) = k] \propto \frac{1}{k^2}$

BA-graphs: clustering coefficient

BA-graphs after t steps

Consider clustering coefficient of vertex v_s after t steps in the construction of a $BA(t, n_0, m)$ graph. **Note:** v_s was added at step $s \leq t$.

$$cc(v_s) = \frac{m-1}{8(\sqrt{t} + \sqrt{s}/m)^2} \left(\ln^2(t) + \frac{4m}{(m-1)^2} \ln^2(s) \right)$$

BA-graphs: clustering coefficient

Note: Fix m and t and vary s :

Comparing clustering coefficients

Issue: Construct an ER graph with same number of vertices and average vertex degree:

$$\begin{aligned}
 \bar{\delta}(G) &= \mathbb{E}[\delta] = \sum_{k=m}^{\infty} k \cdot \mathbb{P}[\delta(u) = k] \\
 &= \sum_{k=m}^{\infty} k \cdot \frac{2m(m+1)}{k(k+1)(k+2)} \\
 &= 2m(m+1) \sum_{k=m}^{\infty} \frac{k}{k(k+1)(k+2)} \\
 &= 2m(m+1) \cdot \frac{1}{m+1} = 2m
 \end{aligned}$$

ER-graph: $\bar{\delta}(G) = p(n-1) \Rightarrow$ choose $p = \frac{2m}{n-1}$

Example

$BA(100,000,0,8)$ -graph has $cc(v) \approx 0.0015$; $ER(100,000,p)$ -graph has $cc(v) \approx 0.00016$

Comparing clustering coefficients

Further comparison: Ratio of $cc(v_s)$ between $BA(N \leq 1\,000\,000\,000, 0, 8)$ -graph to an $ER(N, p)$ -graph

Average path lengths

Observation

$$\bar{d}(BA) = \frac{\ln(n) - \ln(m/2) - 1 - \gamma}{\ln(\ln(n)) + \ln(m/2)} + 1.5$$

with $\gamma \approx 0.5772$ the Euler constant. For $\bar{\delta}(v) = 10$:

Scale-free graphs and robustness

Observation

Scale-free networks have **hubs** making them vulnerable to **targeted attacks**.

Barabási-Albert with tunable clustering

Algorithm

Consider a small graph G_0 with n_0 vertices V_0 and no edges. At each step $s > 0$:

- 1 Add a new vertex v_s to V_{s-1} .
- 2 Select u from V_{s-1} not adjacent to v_s , with probability proportional to $\delta(u)$. Add edge $\langle v_s, u \rangle$.
 - (a) If $m - 1$ edges have been added, continue with Step 3.
 - (b) With probability q : select a vertex w adjacent to u , but not to v_s . If no such vertex exists, continue with Step c. Otherwise, add edge $\langle v_s, w \rangle$ and continue with Step a.
 - (c) Select vertex u' from V_{s-1} not adjacent to v_s with probability proportional to $\delta(u')$. Add edge $\langle v_s, u' \rangle$ and set $u \leftarrow u'$. Continue with Step a.
- 3 If n vertices have been added stop, else go to Step 1.

Barabási-Albert with tunable clustering

Special case: $q = 1$

If we add edges $\langle v_s, w \rangle$ with probability 1, we obtain a previously constructed subgraph.

Recall

$$cc(x) = \begin{cases} 1 & \text{if } x = w_i \\ \frac{2}{k+1} & \text{if } x = u, v_s \end{cases}$$

[genomebiology.com]

- Graphs are ubiquitous
- “Patterns” → regularities that occur in many graphs
- We want a **realistic** and **efficient** graph generator
 - which matches many patterns
 - and would be very useful for simulation studies.

Graph Patterns

► R-MAT matches undirected graphs

Conclusions

The R-MAT graph generator

- ✓ matches the patterns mentioned before
- ✓ along with DGX/lognormal degree distributions → can be shown theoretically
- ✓ exhibits a “Community” effect
- ✓ generates undirected, directed, bipartite and weighted graphs with ease
- ✓ requires only 3 parameters (a,b,c),
- ✓ and, is fast and scalable → $O(E \log N)$

The “DGX”/lognormal distribution

- Deviations from power-laws have been observed [Pennock+ '02]
- These are well-modeled by the DGX distribution [Bi+'01]
- Essentially fits a parabola instead of a line to the log-log plot.

Our Proposed Generator

- R-MAT (Recursive MATrix) [SIAM DM'04]
 - Subdivide the adjacency matrix
 - and choose one quadrant with probability (a,b,c,d)
 - Recurse till we reach a 1*1 cell
 - where we place an edge
 - and repeat for all edges.
