Advantages of concurrent programs

- Reactive programming
  - User can interact with applications while tasks are running, e.g., stopping the transfer of a big file in a web browser.
- Availability of services
  - Long-running tasks need not delay short-running ones, e.g., a web server can serve an entry page while at the same time processing a complex query.
- Parallelism
  - Complex programs can make better use of multiple resources in new multi-core processor architectures, SMPs, LANs or WANs, e.g., scientific/engineering applications, simulations, games, etc.
- Controllability
  - Tasks requiring certain preconditions can suspend and wait until the preconditions hold, then resume execution transparently.

Disadvantages of concurrent programs

- Safety
  - “Nothing bad ever happens”
  - Concurrent tasks should not corrupt consistent state of program
- Liveness
  - “Everything ever happens at all”
  - Tasks should not suspend and indefinitely wait for each other (deadlock).
- Non-determinism
  - Mastering exponential number of interleavings due to different schedules.
- Resource consumption
  - Threads can be expensive. Overhead of scheduling, context-switching, and synchronization.
  - Concurrent programs can run slower than their sequential counterparts even with multiple CPUs!

Overview of concurrent programming

- There are four basic approaches:
  - Sequential programming (no concurrency)
  - Declarative concurrency (streams in a functional language)
  - Message passing with active objects (Erlang, SALSA)
  - Atomic actions on shared state (Java)
- The atomic action approach is the most difficult, yet it is the one you will probably be most exposed to!
- But, if you have the choice, which approach to use?
  - Use the simplest approach that does the job: sequential if that is ok, else declarative concurrency if there is no observable nondeterminism, else message passing if you can get away with it.

Actors/SALSA

- Actor Model
  - A reasoning framework to model concurrent computations
  - Programming abstractions for distributed open systems
- SALSA
  - Simple Actor Language System and Architecture
  - An actor-oriented language for mobile and internet computing
  - Programming abstractions for internet-based concurrency, distribution, mobility, and coordination

SALSA and Java

- SALSA source files are compiled into Java source files before being compiled into Java byte code.
- SALSA programs may take full advantage of the Java API.
Hello World Example

module examples.helloworld;

behavior HelloWorld {
  void act(String[] args) {
    standardOutput <- print("Hello") @
    standardOutput <- println("World!");
  }
}

Hello World Example

• The `act(String[] args)` message handler is similar to the `main(...)` method in Java and is used to bootstrap SALSA programs.

• When a SALSA program is executed, an actor of the given behavior is created and an `act(args)` message is sent to this actor with any given command-line arguments.

• References to `standardOutput`, `standardInput` and `standardError` actors are available to all SALSA actors.

SALSA Support for Actors

• Programmers define `behaviors` for actors.

• Messages are sent asynchronously.

• State is modeled as encapsulated objects/primitive types.

• Messages are modeled as potential method invocations.

• Continuation primitives are used for coordination.

Reference Cell Example

module examples.cell;

behavior Cell {
  Object content;
  Cell(Object initialContent) {
    content = initialContent;
  }
  Object get() { return content; }
  void set(Object newContent) {
    content = newContent;
  }
}

Actor Creation

• To create an actor:

```java
TravelAgent a = new TravelAgent();
```

Message Sending

• To create an actor:

```java
TravelAgent a = new TravelAgent();
```

• To send a message:

```java
a <- book(flight);
```
**Causal order**

- In a sequential program all execution states are totally ordered.
- In a concurrent program all execution states of a given actor are totally ordered.
- The execution state of the concurrent program as a whole is partially ordered.

**Total order**

- In a sequential program all execution states are totally ordered.

**Causal order in the actor model**

- In a concurrent program all execution states of a given actor are totally ordered.
- The execution state of the concurrent program is partially ordered.

**Nondeterminism**

- An execution is nondeterministic if there is a computation step in which there is a choice what to do next.
  
  - Nondeterminism appears naturally when there is asynchronous message passing:
    
    - Messages can arrive or be processed in an order different from the sending order.

**Example of nondeterminism**

Actor \( a \) can receive messages \( m_1() \) and \( m_2() \) in any order.

**Coordination Primitives**

- SALSA provides three main coordination constructs:
  
  - **Token-passing continuations**
    
    - To synchronize concurrent activities
    
    - To notify completion of message processing
    
    - Named tokens enable arbitrary synchronization (data-flow)
  
  - **Join blocks**
    
    - Used for barrier synchronization for multiple concurrent activities
    
    - To obtain results from otherwise independent concurrent processes
  
  - **First-class continuations**
    
    - To delegate producing a result to a third-party actor
Token Passing Continuations

- Ensures that each message in the continuation expression is sent after the previous message has been processed. It also enables the use of a message handler return value as an argument for a later message (through the token keyword).

  - Example:
    
    ```
    a1 <- m1() @
    a2 <- m2() { token } @
    ```

    Send m1 to a1 asking a1 to forward the result of processing m1 to a2 (as the argument of message m2).

Named Tokens

- Tokens can be named to enable more loosely-coupled synchronization

  - Example:
    
    ```
    token t1 = a1 <- m1();
    token t2 = a2 <- m2();
    token t3 = a3 <- m3( t1 );
    token t4 = a4 <- m4( t2 );
    ```

    Sending m1() to a will be delayed until messages m1()..m4() have been processed. m2() can proceed concurrently with m2().

Causal order in the actor model

- Provide a mechanism for synchronizing the processing of a set of messages.
- Set of results is sent along as a token containing an array of results.

  - Example:
    
    ```
    Actor[] actors = { searcher0, searcher1, searcher2, searcher3 };
    join { 
        for (int i=0; i < actors.length; i++){
            actors[i] <- find( phrase );
        }
    } @
    ```

    Send the find( phrase ) message to each actor in actors[] then after all have completed send the result to resultActor as the argument of an output(…, message).
### First Class Continuations

- Enable actors to delegate computation to a third party independently of the processing context.
- For example:

```java
int m(...) {
    b <- n(...) @ currentContinuation;
}
```

Ask (delegate) actor `b` to respond to this message `m` on behalf of current actor `(self)` by processing its own message `n`.

---

### Delegate Example

```java
module examples.fibonacci;

behavior Calculator {
    int fib(int n) {
        Fibonacci f = new Fibonacci(n);
        f <- compute() @ currentContinuation;
    }
    int add(int n1, int n2) (return n1+n2);
    void act(String args[]) {
        fib(15) @ standardOutput <- println(token);
        fib(5) @ add(token,3) @ standardOutput <- println(token);
    }
}
```

---

### Fibonacci Example

```java
module examples.fibonacci;

behavior Fibonacci {
    int n;
    Fibonacci(int n)
        { this.n = n; }
    int add(int x, int y) { return x + y; }
    int compute(int n) {
        if (n == 0) return 0;
        else if (n <= 2) return 1;
        else {
            Fibonacci fib1 = new Fibonacci(n-1);
            Fibonacci fib2 = new Fibonacci(n-2);
            token x = fib1 <- compute();
            token y = fib2 <- compute();
            add(x,y) @ currentContinuation;
        }
    }
    void act(String args[]) {
        n = Integer.parseInt(args[0]);
        compute() @ standardOutput <- println(token);
    }
}
```

---

### Fibonacci Example 2

```java
module examples.fibonacci2;

behavior Fibonacci {
    int add(int x, int y) { return x + y; }
    int compute(int n) {
        if (n == 0) return 0;
        else if (n <= 2) return 1;
        else {
            Fibonacci fib = new Fibonacci();
            compute(n-1) @ add(token, compute(n-2) @ add(token, compute(n-2)) @ currentContinuation);
        }
    }
    void act(String args[]) {
        String[] args2 = args[2].split("");
        compute() @ standardOutput <- println(token);
    }
}
```

---

### Execution of salsa Fibonacci 6

Create new actor

Synchronize on result

Non-blocked actor
Exercises

66. How would you implement the join continuation linguistic abstraction in terms of message passing?

67. Download and execute the CellTester.salsa example.

68. *Write a solution to the Flavius Josephus problem in SALSA. A description of the problem is at VRH Section 7.8.3 (page 358).
