- Discussion of Website & Syllabus:
  
  http://www.cs.rpi.edu/academics/courses/fall10/ds/

- Quick Review/Overview of C/C++ Programming, Algorithm Analysis, Order Notation

1.1 Example 1: Temperature Conversion

/* This program converts a Fahrenheit temperature to a Celsius temperature and decides
   if the temperature is above the boiling point or below the freezing point */
#include <iostream>

int main() {
  // Request and input a temperature.
  std::cout << "Please enter a Fahrenheit temperature: ";
  float fahrenheit_temp;
  std::cin >> fahrenheit_temp;
  // Convert it to Celsius and output it.
  float celsius_temp = (fahrenheit_temp - 32) * 5.0 / 9.0;
  std::cout << "The equivalent Celsius temperature is " << celsius_temp << " degrees." << std::endl;
  // Output a message if the temperature is above boiling or below freezing.
  const int BoilingPointC = 100;
  const int FreezingPointC = 0;
  if (celsius_temp > BoilingPointC)
    std::cout << "That is above the boiling point of water.\n";
  else if (celsius_temp < FreezingPointC)
    std::cout << "That is below the freezing point of water.\n";
  return 0;
}

1.2 Basic Syntax

- Comments are indicated using // for single line comments and /* and */ for multi-line comments.

- #include asks the compiler for parts of the standard library and other code that we wish to use (e.g. the input/output stream function std::cout).

- int main() is a necessary component of all C++ programs; it returns a value (integer in this case) and it may have parameters.

- { }: the curly braces indicate to C++ to treat everything between them as a unit.

1.3 The Standard Library

- The standard library is not a part of the core C++ language. Instead it contains types and functions that are important extensions. We will use the standard library to such a great extent that it will feel like part of the C++ core language.

- streams are the first component of the standard library that we see.

- std is a namespace that contains the standard library.

- std::cout and std::endl are defined in the standard library (in particular, in the standard library header file iostream).
1.4 C++ vs. Java

The following is provided as additional material for students who have learned Java and are now learning C++.

- In Java, everything is an object and everything “inherits” from java.lang.Object. In C++, functions can exist outside of classes. In particular, the main function is never part of a class.
- Source code file organization in C++ does not need to be related to class organization as it does in Java. On the other hand, creating one C++ class (when we get to classes) per file is the preferred organization, with the main function in a separate file on its own or with a few helper functions.

1.5 Variables and Constants

- A variable is an object with a name (a C++ identifier such as fahrenheit_temp or celsius_temp).
- An object is computer memory that has a type.
- A type is a structure to memory and a set of operations.
- For example, a float is an object and each float variable is assigned to 4 bytes of memory, and this memory is formatted according floating point standards for what represents the exponent and mantissa. There are many operations defined on floats, including addition, subtraction, etc.
- A constant (such as BoilingPointC and FreezingPointC) is an object with a name, but a constant object may not be changed once it is defined (and initialized). Any operations on the integer type may be applied to a constant int, except operations that change the value.

1.6 Expressions, Assignments and Statements

Consider the statement: float celsius_temp = (fahrenheit_temp - 32) * 5.0 / 9.0;

- The calculation on the right hand side of the = is an expression. You should review the definition of C++ arithmetic expressions and operator precedence from any reference textbook. The rules are pretty much the same in C++ and in Java.
- The value of this expression is assigned (stored in the memory location) of the newly created float variable celsius_temp.

1.7 Example 2: Julian Day

// Convert a day and month within a given year to the Julian day.
#include <iostream>
using namespace std; // Eliminates the need for std::

// Returns true if the given year is a leap year and returns false otherwise.
bool is_leap_year(int year) {
    return year % 4 == 0 && (year % 100 != 0 || year % 400 == 0);
}

// Returns the Julian day associated with the given month and day of the year.
int julian_day(int month, int day, int year) {
    int jday = 0;
    for (unsigned int m=1; m<month; ++m) {
        jday += DaysInMonth[m];
        if (m == 2 && is_leap_year(year)) ++jday; // February 29th
    }
    jday += day;
    return jday;
}

int main() {
    cout << "Please enter three integers (a month, a day and a year): ";
    int month, day, year;
    cin >> month >> day >> year;
    cout << "That is Julian day " << julian_day(month, day, year) << endl;
    return 0;
}
1.8 Conditionals and IF statements

- The general form of an if-else statement is
  
  ```
  if (conditional-expression)
      statement;
  else
      statement;
  ```

- Each statement may be a single statement, such as the cout statement above, a structured statement, or a compound statement delimited by {...} In Example 1, the second if is actually a structured statement that is part of the else of the first if.

- Students should review the rules of logical expressions and conditionals. These rules and the meaning of the if-else structure are essentially the same in Java and in C++.

1.9 Arrays and Constant Arrays

- An array is a fixed-length, consecutive sequence of objects all of the same type. The following declares an array of 15 double values:
  
  ```
  double a[15];
  ```

- The values are accessed through subscripting operations. The following code assigns the value 3.14159 to location i=5 of the array. Here i is the subscript or index.
  
  ```
  int i = 5;
  a[i] = 3.14159;
  ```

- C++ array indexing starts at 0.

- Arrays are fixed size, and each array knows NOTHING about its own size. The programmer must write code that keeps track of the size of each array. Very soon we will see a standard library generalization of arrays, called vectors, which do not have these restrictions.

- In the statement:
  
  ```
  ```

  - DaysInMonth is an array of 13 constant integers.
  - The list of values within the braces initializes the 13 values of the array, so that DaysInMonth[0] == 0, DaysInMonth[1]==31, etc.
  - The array is global, meaning that it is accessible in all functions within the code (after the line in which the array is declared). Global constants such as this array are usually fine, whereas global variables are generally a VERY bad idea.

1.10 Functions and Arguments

- Functions are used to:
  
  - Break code up into modules for ease of programming and testing, and for ease of reading by other people (never, ever, under-estimate the importance of this!).
  - Create code that is reusable at several places in one program and by several programs.

- Each function has a sequence of parameters and a return type. The function declaration or prototype below has a return type of int and three parameters, each of type int:
  
  ```
  int julian_day(int month, int day, int year)
  ```

- The order of the parameters in the calling function (the main function in this example) must match the order of the parameters in the function prototype.
1.11 Example 3: Julian Date to Month/Day

// Convert a Julian day in a given year to the associated month and day.
#include <iostream>
using namespace std;

// Function prototypes. In general, if function A calls function B, function B
// must be defined "before" A or function B’s prototype must be specified before A.
bool is_leap_year(int year);
void month_and_day(int julian_day, int year, int & month, int & day);
void output_month_name(int month);

int main() { // The main function handles the I/O.
    int julian, year, month, day_in_month;
    cout << "Please enter two integers giving the Julian date and the year: ";
    cin >> julian >> year;
    month_and_day(julian, year, month, day_in_month);
    cout << "The date is " << output_month_name(month) << ", " << day_in_month << ", " << year << endl;
    return 0;
}

bool is_leap_year(int year) {
    return year % 4 == 0 && (year % 100 != 0 || year % 400 == 0);
}

void month_and_day(int julian_day, int year, int & month, int & day) {
    bool month_found = false;
    month = 1;
    // Subtracting the days in each month from the Julian day, until the
    // remaining days is less than or equal to the total days in the month.
    while (!month_found) {
        int days_this_month = DaysInMonth[month];
        if (month == 2 && is_leap_year(year)) // Add one if it is a leap year.
            ++days_this_month;
        if (julian_day <= days_this_month)
            month_found = true; // Done!
        else {
            julian_day -= days_this_month;
            ++month;
        }
    }
    day = julian_day;
}

void output_month_name(int month) { // Output a string giving the name of the month.
    switch (month) {
    case 1: cout << "January"; break;
    case 2: cout << "February"; break;
    case 3: cout << "March"; break;
    case 4: cout << "April"; break;
    case 5: cout << "May"; break;
    case 6: cout << "June"; break;
    case 7: cout << "July"; break;
    case 8: cout << "August"; break;
    case 9: cout << "September"; break;
    case 10: cout << "October"; break;
    case 11: cout << "November"; break;
    case 12: cout << "December"; break;
    default: cout << "Illegal month";
    }
1.12 for Loops

- Here is the basic form of a for loop:
  
  ```c
  for (expr1; expr2; expr3)
  statement;
  ```

  - `expr1` is the initial expression executed at the start before the loop iterations begin;
  - `expr2` is the test applied before the beginning of each loop iteration, the loop ends when this expression evaluates to `false` or `0`;
  - `expr3` is evaluated at the very end of each iteration;
  - `statement` is the “loop body”

- The for loop below from the `julian_day` function, adds the days in the months 1..month-1, and adds an extra day for Februarys that are in leap years.
  ```c
  for (unsigned int m=1; m<month; ++m) {
    jday += DaysInMonth[m];
    if (m == 2 && is_leap_year(year)) ++jday; // February 29th
  }
  ```

- for loops are essentially the same in Java and in C++.

1.13 A More Difficult Logic Example

Consider the code in the function `is_leap_year`:

```c
return year % 4 == 0 && (year % 100 != 0 || year % 400 == 0);
```

Note that the function will not work properly if the parentheses are removed, in part because `&&` has higher precedence than `||`.

1.14 Month And Day Function

- A `bool` variable (which can take on only the values `true` and `false`) called `month_found` is used as a flag to indicate when the loop should end.

- The first part of the loop body calculates the number of days in the current month (starting at one for January), including a special addition of 1 to the number of days for a February (`month == 2`) in a leap year.

- The second half decides if we’ve found the right month. If not, the number of days in the current month is subtracted from the remaining Julian days, and the month is incremented.

1.15 Value Parameters and Reference Parameters

Consider the line in the main function that calls `month_and_day`:

```c
month_and_day(julian, year, month, day_in_month);
```

and consider the function prototype:

```c
void month_and_day(int julian_day, int year, int & month, int & day)
```

Note in particular the `&` in front of the third and fourth parameters.

- The first two parameters are value parameters.
  
  - These are essentially local variables (in the function) whose initial values are copies of the values of the corresponding argument in the function call.
  
  - Thus, the value of `julian` from the main function is used to initialize `julian_day` in function `month_and_day`.
  
  - Changes to value parameters do NOT change the corresponding argument in the calling function (`main` in this example).
• The second two parameters are *reference parameters*, as indicated by the &.
  – Reference parameters are just aliases for their corresponding arguments. No new variable are created.
  – As a result, changes to reference parameters are changes to the corresponding variables (arguments) in
    the calling function.
• In general, the “Rules of Thumb” for using value and reference parameters:
  – When a function (e.g. *is_leap_year*) needs to provide just one result, make that result the return value
    of the function and pass other parameters by value.
  – When a function needs to provide more than one result (e.g. *month_and_day*), these results should be
    returned using multiple reference parameters.

1.16 Arrays as Function Arguments

• What does the following function do?
  ```
  void do_it (double a[], int n) {
      for (int i = 0; i < n; ++i)
          if (a[i] < 0) a[i] *= -1;
  }
  ```
• Changes made to array *a* are permanent, even though *a* is a value parameter! Why? Because what’s passed
  by value is *the memory location of the start of the array*. The entries in the array are not copied, and therefore
  changes to these entries are permanent.
• The number of locations in the array to work on — the value parameter *n* — must be passed as well because
  arrays have no idea about their own size.

1.17 Exercises
1. What would be the output of the above program if the main program call to *month_and_day* was changed to:
   ```
   month_and_day(julian, year, day_in_month, month);
   ```
   and the user provided input that resulted in *julian == 50* and *year == 2011*? What would be the additional
   output if we added this statement immediately after the function call in the main function?
   ```
   cout << julian << endl;
   ```
2. What is the output of the following code?
  ```
  void swap(double x, double &y) {
      double temp = x;
      x = y;
      y = temp;
  }
  ```
    ```
  int main() {
      double a = 15.0, b=20.0;
      cout << "a = " << a << " b= " << b << endl;
      swap (a, b);
      cout << "a = " << a << " b= " << b << endl;
      return 0;
  }
  ```

1.18 Scope

• The *scope* of a name (identifier) is the part of the program in which it has meaning. Curly braces, { }, establish
  a new scope — this includes functions and compound statements.
• Scopes may be nested.
• Identifiers may be re-used as long as they are in different scopes. Identifiers (variables or constants) within a
  scope hide identifiers within an outer scope having the same name. This does not change the values of hidden
  variables or constants — they are just not accessible.
• When a } is reached, a scope ends. All variables and constants (and other identifiers) declared in the scope are
  eliminated, and identifiers from an outer scope that were hidden become accessible again in code that follows
  the end of the scope.
• The operator :: (namespaces) establishes a scope as well.
1.19 Algorithm Analysis

*Why should we bother?*

- We want to do better than just implementing and testing every idea we have.
- We want to know why one algorithm is better than another.
- We want to know the best we can do. (This is often quite hard.)

*How do we do it?* There are several options, including:

- Don’t do any analysis; just use the first algorithm you can think of that works.
- Implement and time algorithms to choose the best.
- Analyze algorithms by counting operations while assigning different weights to different types of operations based on how long each takes.
- Analyze algorithms by assuming each operation requires the same amount of time. Count the total number of operations, and then multiply this count by the average cost of an operation.

1.20 Exercise: Counting Example

- Suppose `arr` is an array of `n` doubles. Here is a simple fragment of code to sum of the values in the array:

```java
double sum = 0;
for (int i=0; i<n; ++i)
    sum += arr[i];
```

- What is the total number of operations performed in executing this fragment? Come up with a function describing the number of operations *in terms of* `n`.

1.21 Exercise: Which Algorithm is Best?

An venture capitalist is trying to decide which of 3 startup companies to invest in and has asked for your help. Here’s the timing data for their prototype software on some different size test cases:

<table>
<thead>
<tr>
<th>n</th>
<th>foo-a</th>
<th>foo-b</th>
<th>foo-c</th>
</tr>
</thead>
<tbody>
<tr>
<td>10</td>
<td>10 u-sec</td>
<td>5 u-sec</td>
<td>1 u-sec</td>
</tr>
<tr>
<td>20</td>
<td>13 u-sec</td>
<td>10 u-sec</td>
<td>8 u-sec</td>
</tr>
<tr>
<td>30</td>
<td>15 u-sec</td>
<td>15 u-sec</td>
<td>27 u-sec</td>
</tr>
<tr>
<td>100</td>
<td>20 u-sec</td>
<td>50 u-sec</td>
<td>1000 u-sec</td>
</tr>
<tr>
<td>1000</td>
<td>?</td>
<td>?</td>
<td>?</td>
</tr>
</tbody>
</table>

Which company has the “best” algorithm?

1.22 Order Notation Definition

*In this course we will focus on the intuition of order notation. This topic will be covered again, in more depth, in later computer science courses.*

- Definition: Algorithm A is order $f(n)$ — denoted $O(f(n))$ — if constants $k$ and $n_0$ exist such that A requires no more than $k * f(n)$ time units (operations) to solve a problem of size $n \geq n_0$.
- For example, algorithms requiring $3n + 2$, $5n - 3$, and $14 + 17n$ operations are all $O(n)$. This is because we can select values for $k$ and $n_0$ such that the definition above holds. (What values?) Likewise, algorithms requiring $n^2/10 + 15n - 3$ and $10000 + 35n^2$ are all $O(n^2)$.
- Intuitively, we determine the order by finding the asymptotically dominant term (function of $n$) and throwing out the leading constant. This term could involve logarithmic or exponential functions of $n$. Implications for analysis:
  - We don’t need to quibble about small differences in the numbers of operations.
  - We also do not need to worry about the different costs of different types of operations.
  - We don’t produce an actual time. We just obtain a rough count of the number of operations. This count is used for comparison purposes.
- In practice, this makes analysis relatively simple, quick and (sometimes unfortunately) rough.
1.23 Common Orders of Magnitude

- \( O(1) \), a.k.a. CONSTANT: The number of operations is independent of the size of the problem. e.g., compute quadratic root.
- \( O(\log n) \), a.k.a. LOGARITHMIC. e.g., dictionary lookup, binary search.
- \( O(n) \), a.k.a. LINEAR. e.g., sum up a list.
- \( O(n \log n) \), e.g., sorting.
- \( O(n^2), O(n^3), O(n^k) \), a.k.a. POLYNOMIAL. e.g., find closest pair of points.
- \( O(2^n), O(k^n) \), a.k.a. EXPONENTIAL. e.g., Fibonacci, playing chess.

1.24 Exercise: A Slightly Harder Example

- Here’s an algorithm to determine if the value stored in variable \( x \) is also in an array called \( \text{foo} \). Can you analyze it? What did you do about the \( \text{if} \) statement? What did you assume about where the value stored in \( x \) occurs in the array (if at all)?

```c++
int loc=0;
bool found = false;
while (!found && loc < n) {
    if (x == foo[loc]) found = true;
    else loc++;
}
if (found) cout << "It is there!\n";
```

1.25 Best-Case, Average-Case and Worst-Case Analysis

- For a given fixed size array, we might want to know:
  - The fewest number of operations (best case) that might occur.
  - The average number of operations (average case) that will occur.
  - The maximum number of operations (worst case) that can occur.

- The last is the most common. The first is rarely used.
- On the previous algorithm, the best case is \( O(1) \), but the average case and worst case are both \( O(n) \).

1.26 Approaching An Analysis Problem

- Decide the important variable (or variables) that determine the “size” of the problem. For arrays and other “container classes” this will generally be the number of values stored.
- Decide what to count. The order notation helps us here.
  - If each loop iteration does a fixed (or bounded) amount of work, then we only need to count the number of loop iterations.
  - We might also count specific operations. For example, in the previous exercise, we could count the number of comparisons.
- Do the count and use order notation to describe the result.

1.27 Exercises: Order Notation

For each version below, give an order notation estimate of the number of operations as a function of \( n \):

1. \( \text{int count}=0; \)
   \( \text{for (int i=0; i<n; ++i)} \)
   \( \text{for (int j=0; j<n; ++j)} \)
   \( \text{++count;} \)

2. \( \text{int count}=0; \)
   \( \text{for (int i=0; i<n; ++i)} \)
   \( \text{++count;} \)
   \( \text{for (int j=i; j<n; ++j)} \)
   \( \text{++count;} \)

3. \( \text{int count}=0; \)
   \( \text{for (int i=0; i<n; ++i)} \)
   \( \text{for (int j=0; j<n; ++j)} \)
   \( \text{++count;} \)
Important: It will be assumed that you have read the following statement thoroughly. If you have any questions, contact the instructor or the TAs immediately. Please sign this form and give it to your TA during your first lab section.

CSCI-1200 Data Structures

Academic Integrity Policy

Copying, communicating, or using disallowed materials during an exam is cheating, of course. Students caught cheating on an exam will receive an F in the course and will be reported to the Dean of Students. Students are allowed to assist each other in labs and ask the TAs for help, but each student must write up their own lab solutions.

Academic integrity is a more complicated issue for individual programming assignments, but one we take very seriously. Students naturally want to work together, and it is clear they learn a great deal by doing so. Getting help is often the best way to interpret error messages and find bugs, even for experienced programmers. In response to this, the following rules will be in force for programming assignments:

- Students are allowed to work together in designing high level algorithms, in interpreting error messages, and in discussing strategies for testing and finding bugs, but NOT in writing code or pseudocode. Detailed algorithms and implementation must be done individually.

- Students may not jointly write code or pseudocode, may not share code or pseudocode, may not copy code or pseudocode, and may not discuss code or pseudocode in detail (line-by-line or loop-by-loop) while it is being written or afterwards. This extends up to two days after the submission deadline.

- Similarily, students may not receive detailed help on their code from individuals outside the course. This restriction includes tutors, students from prior terms, and internet resources.

- Students may not show their code to other students as a means of helping them. Sometimes good students who feel sorry for struggling students are tempted to provide them with “just a peek” at their code. Such “peeks” often turn into extensive copying, despite prior claims of good intentions.

- Students may not leave their code (either electronic versions or printed copies) in publicly accessible areas. Students may not share computers in any way when there is an assignment pending.

We use an automatic code comparison tool to help spot assignments that have been submitted in violation of these rules. The tool takes all assignments from all sections and all prior terms and compares them, highlighting regions of the code that are similar. Code submitted by students who followed the rules produces less than 10% overlap. Code submitted by students who broke the rules produces anywhere from about 30% to 100% overlap.

We (the instructor and the TAs) check flagged pairs of assignments very carefully ourselves, and make our own judgment about which students violated the rules of academic integrity on programming assignments. When we believe an incident of academic dishonesty has occurred, we contact the students involved. All students caught cheating on a programming assignment (both the copier and the provider) will be punished. The standard punishment for the first offense is a 0 on the assignment and a letter grade reduction on the final semester grade. Students whose violations are more flagrant will receive a higher penalty. For example, a student who outright steals another student’s code will receive an F in the course immediately. Students caught a second time will receive an immediate F, regardless of circumstances. Each incident will be reported to the Dean of Students.

Refer to the Rensselaer Handbook of Student Rights and Responsibilities for further discussion of academic dishonesty. Note that: “Students found in violation of the academic dishonesty policy are prohibited from dropping the course in order to avoid the academic penalty.”

In the past 6 fall semesters, a total of 41 students taking CSCI 1200 were found in violation of the academic integrity policy and were punished.
