Lambda Calculus (PDCS 2)
alpha-renaming, beta reduction, eta conversion,
applicative and normal evaluation orders, Church-Rosser theorem, combinators, booleans

Carlos Varela
Rensselaer Polytechnic Institute

September 2, 2016
The syntax of a λ-calculus expression is as follows:

\[
e ::= v \quad \text{variable} \\
| \lambda v.e \quad \text{functional abstraction} \\
| (e e) \quad \text{function application}
\]

The semantics of a λ-calculus expression is called beta-reduction:

\[
(\lambda x.E \ M) \Rightarrow E\{M/x\}
\]

where we alpha-rename the lambda abstraction E if necessary to avoid capturing free variables in M.
Function Composition in Lambda Calculus

S: \( \lambda x. (s \ x) \) (Square)
I: \( \lambda x. (i \ x) \) (Increment)
C: \( \lambda f. \lambda g. \lambda x. (f \ (g \ x)) \) (Function Composition)

\[(\lambda f. \lambda g. \lambda x. (f \ (g \ x))) \ (\lambda x. (s \ x)) \ (\lambda x. (i \ x)) \]
\[\Rightarrow (\lambda g. \lambda x. (\lambda x. (s \ x) \ (g \ x)) \ (\lambda x. (i \ x) \ x)) \]
\[\Rightarrow \lambda x. (\lambda x. (s \ x) \ (\lambda x. (i \ x) \ x)) \]
\[\Rightarrow \lambda x. (\lambda x. (s \ x) \ (i \ x)) \]
\[\Rightarrow \lambda x. (s \ (i \ x)) \]

Recall semantics rule:

\((\lambda x. E\ M) \Rightarrow E\{M/x}\)
Order of Evaluation in the Lambda Calculus

Does the order of evaluation change the final result?
Consider:

\[ \lambda x. (\lambda x. (s x) (\lambda x.(i x) x)) \]

There are two possible evaluation orders:

\[ \lambda x. (\lambda x. (s x) (\lambda x.(i x) x)) \]
\[ \Rightarrow \lambda x. (\lambda x. (s x) (i x)) \]
\[ \Rightarrow \lambda x. (s (i x)) \]

and:

\[ \lambda x. (\lambda x. (s x) (\lambda x.(i x) x)) \]
\[ \Rightarrow \lambda x. (s (\lambda x.(i x) x)) \]
\[ \Rightarrow \lambda x. (s (i x)) \]

Is the final result always the same?

Recall semantics rule:

\[ (\lambda x. E M) \Rightarrow E{M/x} \]

Applicative Order

Normal Order
Church-Rosser Theorem

If a lambda calculus expression can be evaluated in two different ways and both ways terminate, both ways will yield the same result.

Also called the *diamond* or *confluence* property.

Furthermore, if there is a way for an expression evaluation to terminate, using normal order will cause termination.
Order of Evaluation and Termination

Consider:

\[(\lambda x. y (\lambda x. (x \ x) \ \lambda x. (x \ x)))\]

There are two possible evaluation orders:

- \[(\lambda x. y (\lambda x. (x \ x) \ \lambda x. (x \ x))) \Rightarrow (\lambda x. y (\lambda x. (x \ x) \ \lambda x. (x \ x)))\]

and:

\[(\lambda x. y (\lambda x. (x \ x) \ \lambda x. (x \ x))) \Rightarrow y\]

Recall semantics rule:

\[(\lambda x. E \ M) \Rightarrow E\{M/x\}\]

Applicative Order

Normal Order

In this example, normal order terminates whereas applicative order does not.
The lambda functional abstraction is the only syntactic construct that \textit{binds} variables. That is, in an expression of the form:

\[ \lambda v. e \]

we say that occurrences of variable \( v \) in expression \( e \) are \textit{bound}. All other variable occurrences are said to be \textit{free}.

E.g.,

\[(\lambda x. \lambda y. (x y) (y w))\]
Why $\alpha$-renaming?

Alpha renaming is used to prevent capturing free occurrences of variables when reducing a lambda calculus expression, e.g.,

\[
(\lambda x. \lambda y. (x y) (y w))
\Rightarrow \lambda y. ((y w) y)
\]

This reduction **erroneously** captures the free occurrence of $y$.

A correct reduction first renames $y$ to $z$, (or any other *fresh* variable) e.g.,

\[
(\lambda x. \lambda y. (x y) (y w))
\Rightarrow (\lambda x. \lambda z. (x z) (y w))
\Rightarrow \lambda z. ((y w) z)
\]

where $y$ remains *free*.
Alpha renaming is used to prevent capturing free occurrences of variables when beta-reducing a lambda calculus expression.

In the following, we rename $x$ to $z$, (or any other fresh variable):

$$(\lambda x. (y x) x)$$

$$\xrightarrow{\alpha} (\lambda z. (y z) x)$$

Only bound variables can be renamed. No free variables can be captured (become bound) in the process. For example, we cannot alpha-rename $x$ to $y$. 
\( \beta \)-reduction

\[
(\lambda x. E \ M) \xrightarrow{\beta} E\{M/x\}
\]

Beta-reduction may require alpha renaming to prevent capturing free variable occurrences. For example:

\[
(\lambda x. \lambda y. (x \ y) (y \ w))
\]

\[
\xrightarrow{\alpha} (\lambda x. \lambda z. (x \ z) (y \ w))
\]

\[
\xrightarrow{\beta} \lambda z. ((y \ w) \ z)
\]

Where the free \( y \) remains free. 
\[ \lambda x. (E \ x) \stackrel{\eta}{\rightarrow} E \]

if \( x \) is \textit{not} free in \( E \).

For example:

\[ (\lambda x. \lambda y. (x \ y) \ (y \ w)) \]

\[ \xrightarrow{\alpha} (\lambda x. \lambda z. (x \ z) \ (y \ w)) \]

\[ \xrightarrow{\beta} \lambda z. ((y \ w) \ z) \]

\[ \xrightarrow{\eta} (y \ w) \]
A lambda calculus expression with *no free variables* is called a *combinator*. For example:

I: \( \lambda x.x \) (Identity)

App: \( \lambda f.\lambda x. (f x) \) (Application)

C: \( \lambda f.\lambda g.\lambda x. (f (g x)) \) (Composition)

L: \( (\lambda x. (x x) \lambda x. (x x)) \) (Loop)

Cur: \( \lambda f.\lambda x.\lambda y. ((f x) y) \) (Currying)

Seq: \( \lambda x.\lambda y. (\lambda z. y x) \) (Sequencing--normal order)

ASeq: \( \lambda x.\lambda y. (y x) \) (Sequencing--applicative order)

where \( y \) denotes a *thunk*, i.e., a lambda abstraction wrapping the second expression to evaluate.

The meaning of a combinator is always the same independently of its context.
Combinators in Functional Programming Languages

Functional programming languages have a syntactic form for lambda abstractions. For example the identity combinator:

\[ \lambda x.x \]

can be written in Oz as follows:

\[ \text{fun} \{ X \} \ X \ \text{end} \]

in Haskell as follows:

\[ \lambda x \to x \]

and in Scheme as follows:

\[ (\text{lambda}(x) \ x) \]
The currying combinator can be written in Oz as follows:

```
fun {$ F}
  fun {$ X}
    fun {$ Y}
      {F X Y}
    end
  end
end
```

It takes a function of two arguments, F, and returns its curried version, e.g.,

```
{{Curry Plus} 2} 3} ⇒ 5
```
Booleans and Branching (\textit{if}) in \(\lambda\) Calculus

\begin{align*}
|\text{true}| & : \lambda x. \lambda y. x \quad \text{(True)} \\
|\text{false}| & : \lambda x. \lambda y. y \quad \text{(False)} \\
|\text{if}| & : \lambda b. \lambda t. \lambda e. ((b \ t) \ e) \quad \text{(If)}
\end{align*}

Recall semantics rule:
\[ (\lambda x. E \ M) \Rightarrow E\{M/x\} \]

\begin{align*}
(((\text{if true}) \ a) \ b) & \\
\Rightarrow & ((\lambda b. \lambda t. \lambda e. (b \ t) \ e) \lambda x. \lambda y. x) \ a \ b) \\
\Rightarrow & ((\lambda t. \lambda e. (\lambda x. \lambda y. x \ t) \ e) \ a) \ b) \\
\Rightarrow & (\lambda e. ((\lambda x. \lambda y. x \ a) \ e) \ b) \\
\Rightarrow & ((\lambda x. \lambda y. x \ a) \ b) \\
\Rightarrow & (\lambda y. a \ b) \\
\Rightarrow & a
\end{align*}
