Review from Lecture 7

- Algorithm Analysis, Formal Definition of Big O Notation
- (Didn’t get to all of the... ) Lots of examples!

Today

- Another vector operation: pop_back
- Erasing items from vectors is inefficient!
- Iterators and iterator operations
- STL lists are a different sequential container class.
- Returning references to member variables from member functions
- Vec iterator implementation

Optional Reading: Ford & Topp Ch 6; Koenig & Moo, Sections 5.1-5.5

8.1 Another STL vector operation: pop_back

- We have seen how push_back adds a value to the end of a vector, increasing the size of the vector by 1. There is a corresponding function called pop_back, which removes the last item in a vector, reducing the size by 1.

- There are also vector functions called front and back which denote (and thereby provide access to) the first and last item in the vector, allowing them to be changed. For example:

  ```cpp
define vector<int> a(5,1); // a has 5 values, all 1
  a.pop_back(); // a now has 4 values
  a.front() = 3; // equivalent to the statement, a[0] = 3;
  a.back() = -2; // equivalent to the statement, a[a.size()-1] = -2;
```

8.2 Motivating Example: Course Enrollment and Waiting List

- This program maintains the class list and the waiting list for a single course. The program is structured to handle interactive input. Error checking ensures that the input is valid.
- Vectors store the enrolled students and the waiting students. The main work is done in the two functions enroll_student and remove_student.
- The invariant on the loop in the main function determines how these functions must behave.

8.3 Exercises

1. Write erase_from_vector. This function removes the value at index location i from a vector of strings. The size of the vector should be reduced by one when the function is finished.

   ```cpp
   // Remove the value at index location i from a vector of strings. The
   // size of the vector should be reduced by one when the function is finished.
   void erase_from_vector(unsigned int i, vector<string>& v) {
   
   }
   ```

2. Give the big O notation estimate of the average cost of erase_from_vector, pop_back, and push_back.
# include <algorithm>
# include <iostream>
# include <string>
# include <vector>

// Enroll a student if there is room and the student is not already in course or on waiting list.

void enroll_student(const std::string& id, unsigned int max_students, std::vector<std::string>& enrolled, std::vector<std::string>& waiting) {
    // Check to see if the student is already enrolled.
    if (enrolled.size() < max_students) {
        cout << "Student " << id << " added.\n" << endl;
        enrolled.push_back(id);
    } else {
        return;
    }
}

// Remove a student from the course or from the waiting list. If removing the student from the
// course opens up a slot, then the first person on the waiting list is placed in the course.

void remove_student(const std::string& id, unsigned int max_students, std::vector<std::string>& enrolled, std::vector<std::string>& waiting) {
    // Check to see if the student is on the course list.
    if (!found) {
        // Remove the student and see if a student can be taken from the waiting list.
        erase_from_vector(loc, enrolled);
        cout << "Student " << id << " removed from the course.\n" << endl;
        if (waiting.size() > 0) {
            enrolled.push_back(waiting[0]);
            cout << "Student " << waiting[0] << " added to the course from the waiting list.\n" << endl;
            erase_from_vector(0, waiting);
        }
    } else {
        cout << enrolled.size() << " students are now in the course.\n" << endl;
    }
}

// Check to see if the student is on the waiting list.

void erase_from_vector(unsigned int loc, std::vector<std::string>& v) {
    // Exercise: Implement this function
}

int main() {
    // Read in the maximum number of students in the course
    unsigned int max_students;
    cin >> max_students;
    // Initialize the vectors
    std::vector<std::string> enrolled; std::vector<std::string> waiting;
    // Invariant:
    // (1) enrolled contains the students already in the course,
    // (2) waiting contains students who will be admitted (in the order of request) if a spot opens up
    // (3) enrolled.size() <= max_students,
    // (4) if the course is not filled (enrolled.size() != max_students) then waiting is empty
    // if (cin >> option) ( // if we can't read the input integer, then just fail.
    //    cout << "Illegal input. Good-bye.\n";
    //    return;
    //) else if (option == 2) {
    //    break; // quit by breaking out of the loop.
    //) else if (option is 0 or 1 string id)
    //    cout << "Enter student id: ";
    //    if (cin >> id) {
    //        cout << "Invalid option. Try again.\n";
    //        return;
    //    } else if (option == 0) {
    //        enroll_student(id, max_students, enrolled, waiting);
    //    } else {
    //        remove_student(id, max_students, enrolled, waiting);
    //    } while (true);
    // Some nice output
    sort(enrolled.begin(), enrolled.end());
    cout << "At the end of the enrollment period, the following students are in the class:\n";
    for (unsigned int i=0; i<enrolled.size(); ++i) { cout << enrolled[i] << "\n"; }
    if (!waiting.empty()) {
        cout << "There are students on the waiting list in the following order:\n";
        for (unsigned int i=0; i<waiting.size(); ++i) { cout << waiting[i] << "\n"; }
    } return 0;
}
8.4 What To Do About the Expense of Erasing From a Vector?

- When items are continually being inserted and removed, vectors are not a good choice for the container.
- Instead we need a different sequential container, called a list.
  - This has a “linked” structure that makes the cost of erasing independent of the size.
- We will move toward a list-based implementation of the program in two steps:
  - Rewriting our classlist_vec.cpp code in terms of iterator operations.
  - Replacing vectors with lists

8.5 Iterators

- Here’s the definition (from Koenig & Moo). An iterator:
  - identifies a container and a specific element stored in the container,
  - lets us examine (and change, except for const iterators) the value stored at that element of the container,
  - provides operations for moving (the iterators) between elements in the container,
  - restricts the available operations in ways that correspond to what the container can handle efficiently.
- As we will see, iterators for different container classes have many operations in common. This often makes the switch between containers fairly straightforward from the programmer’s viewpoint.
- Iterators in many ways are generalizations of pointers: many operators / operations defined for pointers are defined for iterators. You should use this to guide your beginning understanding and use of iterators.

8.6 Iterator Declarations and Operations

- Iterator types are declared by the container class. For example,

```cpp
vector<string>::iterator p;
vector<string>::const_iterator q;
```

defines two (uninitialized) iterator variables.

- The dereference operator is used to access the value stored at an element of the container. The code:

```cpp
p = enrolled.begin();
*p = "012312";
```

changes the first entry in the enrolled vector.

- The dereference operator is combined with dot operator for accessing the member variables and member functions of elements stored in containers. Here’s an example using the Student class and students vector from Lecture 4:

```cpp
vector<Student>::iterator i = students.begin();
(*i).compute_averages(0.45);
```

Notes:

- This operation would be illegal if i had been defined as a const_iterator because compute_averages is a non-const member function.
- The parentheses on the *i are required (because of operator precedence).

- There is a “syntactic sugar” for the combination of the dereference operator and the dot operator, which is exactly equivalent:

```cpp
vector<StudentRec>::iterator i = students.begin();
i->compute_averages(0.45);
```

- Just like pointers, iterators can be incremented and decremented using the ++ and -- operators to move to the next or previous element of any container.
- Iterators can be compared using the == and != operators.
• Iterators can be assigned, just like any other variable.

• Vector iterators have several additional operations:
  – Integer values may be added to them or subtracted from them. This leads to statements like
    \[
    \text{enrolled}.\text{erase}((\text{enrolled}.\text{begin()}) + 5);
    \]
  – Vector iterators may be compared using operators like <, <=, etc.
  – For most containers (other than vectors), these “random access” iterator operations are not legal and therefore prevented by the compiler. The reasons will become clear as we look at their implementations.

8.7 Exercise: Revising the Class List Program to Use Iterators

• Now let’s modify the class list program to use iterators. First rewrite the \texttt{erase} from vector to use iterators.

\[
\text{void erase\_from\_vector(vector<string>::iterator \textit{itr}, vector<string}& \textit{v}) { }
\]

\[
}
\]

• \textit{Note}: The STL vector class has a member function that does just this... called \texttt{erase}!
  – Give a sample call to our homemade \texttt{erase\_from\_vector} function:

  \[
  \text{- Give the equivalent statement that instead uses the erase member function:}
  \]

• Now, edit the rest of the file to remove all use of the vector subscripting operator.

8.8 A New Datatype: The list Standard Library Container Class

• Lists are our second standard-library container class. (Vectors were the first.) Both lists & vectors store sequential data that can shrink or grow.

• However, the use of memory is fundamentally different. Vectors are formed as a single contiguous array-like block of memory. Lists are formed as a sequentially linked structure instead.

\[
\text{array/vector:} \quad \begin{array}{cccccc}
7 & 5 & 8 & 1 & 9 \\
0 & 1 & 2 & 3 & 4
\end{array} \quad \text{list:} \quad \begin{array}{cccccc}
7 & 5 & 8 & 1 & 9 \\
7 & \quad 5 & \quad 8 & \quad 1 & \quad 9
\end{array}
\]

• Although the interface (functions called) of lists and vectors and their iterators are quite similar, their implementations are \textbf{VERY} different. Clues to these differences can be seen in the operations that are NOT in common, such as:

  – STL vectors / arrays allow “random-access” / indexing / \texttt{[]} subscripting. We can immediately jump to an arbitrary location within the vector / array.
  – STL lists have no subscripting operation (we can’t use \texttt{[]} to access data). The only way to get to the middle of a list is to follow pointers one link at a time.
  – Lists have \texttt{push\_front} and \texttt{pop\_front} functions in addition to the \texttt{push\_back} and \texttt{pop\_back} functions of vectors.
  – \texttt{erase} and \texttt{insert} in the middle of the STL list is very efficient, independent of the size of the list. Both are implemented by rearranging pointers between the small blocks of memory. (We’ll see this when we discuss the implementation details next week).
We can’t use the same STL sort function we used for vector; we must use a special sort function defined by the STL list type.

```cpp
std::vector<int> my_vec;
std::list<int> my_lst;
// ... put some data in my_vec & my_lst
std::sort(my_vec.begin(),my_vec.end(),optional_compare_function);
my_lst.sort(optional_compare_function);
```

Note: STL list sort member function is just as efficient, \(O(n \log n)\), and will also take the same optional compare function as STL vector.

Several operations invalidate the values of vector iterators, but not list iterators:

- `erase` invalidates all iterators after the point of erasure in vectors;
- `push_back` and `resize` invalidate ALL iterators in a vector

The value of any associated vector iterator must be re-assigned / re-initialized after these operations.

### 8.9 Exercise: Revising the Class List Program to Use Lists (& Iterators)

Now let’s further modify the program to use lists instead of vectors. Because we’ve already switched to iterators, this change will be relatively easy. And now the program will be more efficient!

### 8.10 Erase & Iterators

- STL lists and vectors each have a special member function called `erase`. In particular, given list of ints `s`, consider the example:

```cpp
std::list<int>::iterator p = s.begin();
++p;
std::list<int>::iterator q = s.erase(p);
```

- After the code above is executed:
  - The integer stored in the second entry of the list has been removed.
  - The size of the list has shrunk by one.
  - The iterator `p` does not refer to a valid entry.
  - The iterator `q` refers to the item that was the third entry and is now the second.

![Diagram of list after erase](image)

- To reuse the iterator `p` and make it a valid entry, you will often see the code written:

```cpp
std::list<int>::iterator p = s.begin();
++p;
p = s.erase(p);
```

- Even though the `erase` function has the same syntax for vectors and for list, the vector version is \(O(n)\), whereas the list version is \(O(1)\).

### 8.11 Insert

- Similarly, there is an `insert` function for STL lists that takes an iterator and a value and adds a link in the chain with the new value immediately before the item pointed to by the iterator.

- The call returns an iterator that points to the newly added element. Variants on the basic insert function are also defined.
8.12 Exercise: Using STL list Erase & Insert

Write a function that takes an STL list of integers, lst, and an integer, x. The function should 1) remove all negative numbers from the list, 2) verify that the remaining elements in the list are sorted in increasing order, and 3) insert x into the list such that the order is maintained.

8.13 A common confusion/mistake with STL list iterators

```cpp
std::list<int> lst; lst.push_back(100); lst.push_back(200);
lst.push_back(300); lst.push_back(400); lst.push_back(500);

std::list<int>::iterator itr,itr2,itr3;
itr = lst.begin();// itr is pointing at the 100
++itr; // itr is now pointing at 200
*itr += 1; // 200 becomes 201
// itr += 1; // does not compile! can't advance list iterator like this

itr = lst.end(); // itr is pointing "one past the last legal value" of lst
itr--; // itr is now pointing at 500;
itr2 = itr--; // itr is now pointing at 400, itr2 is still pointing at 500
itr3 = --itr; // itr is now pointing at 300, itr3 is also pointing at 300

// dangerous: decrementing the begin iterator is "undefined behavior"
// (similarly, incrementing the end iterator is also undefined)
// it may seem to work, but break later on this machine or on another machine!
itr = lst.begin();
itr--; // dangerous!
itr++;
assert (*itr == 100); // might seem ok... but rewrite the code to avoid this!
```
