# Sequential declarative computation model

- The single assignment store
  - declarative (dataflow) variables
  - partial values (variables and values are also called *entities*)
- The kernel language syntax
- The **kernel language semantics**
  - The environment: maps textual variable names (variable identifiers) into entities in the store
  - Interpretation (execution) of the kernel language elements (statements) by the use of an abstract machine
  - Abstract machine consists of an execution stack of statements transforming the store

# Kernel language syntax

The following defines the syntax of a statement,  $\langle s \rangle$  denotes a statement

$\langle s \rangle ::=$	<code>skip</code>	<i>empty statement</i>
	<code><math>\langle x \rangle = \langle y \rangle</math></code>	<i>variable-variable binding</i>
	<code><math>\langle x \rangle = \langle v \rangle</math></code>	<i>variable-value binding</i>
	<code><math>\langle s_1 \rangle \langle s_2 \rangle</math></code>	<i>sequential composition</i>
	<code>local <math>\langle x \rangle</math> in <math>\langle s_1 \rangle</math> end</code>	<i>declaration</i>
	<code>if <math>\langle x \rangle</math> then <math>\langle s_1 \rangle</math> else <math>\langle s_2 \rangle</math> end</code>	<i>conditional</i>
	<code>{ <math>\langle x \rangle \langle y_1 \rangle \dots \langle y_n \rangle</math> }</code>	<i>procedural application</i>
	<code>case <math>\langle x \rangle</math> of <math>\langle \text{pattern} \rangle</math> then <math>\langle s_1 \rangle</math> else <math>\langle s_2 \rangle</math> end</code>	<i>pattern matching</i>
$\langle v \rangle ::=$	<code>proc { \$ <math>\langle y_1 \rangle \dots \langle y_n \rangle</math> } <math>\langle s_1 \rangle</math> end   ...</code>	<i>value expression</i>
$\langle \text{pattern} \rangle ::=$	...	

# Examples

- `local X in X = 1 end`
- `local X Y T Z in`  
    `X = 5`  
    `Y = 10`  
    `T = (X >= Y)`  
    `if T then Z = X else Z = Y end`  
    `{Browse Z}`  
`end`
- `local S T in`  
    `S = proc {$ X Y} Y = X*X end`  
    `{S 5 T}`  
    `{Browse T}`  
`end`

# Procedure abstraction

- Any statement can be abstracted to a procedure by selecting a number of the 'free' variable identifiers and enclosing the statement into a procedure with the identifiers as parameters

- `if X >= Y then Z = X else Z = Y end`

- Abstracting over all variables

```
proc {Max X Y Z}
  if X >= Y then Z = X else Z = Y end
end
```

- Abstracting over X and Z

```
proc {LowerBound X Z}
  if X >= Y then Z = X else Z = Y end
end
```

# Computations (abstract machine)

- A computation defines how the execution state is transformed step by step from the initial state to the final state
- A *single assignment store*  $\sigma$  is a set of store variables, a variable may be unbound, bound to a partial value, or bound to a group of other variables
- An *environment*  $E$  is mapping from variable identifiers to variables or values in  $\sigma$ , e.g.  $\{X \rightarrow x_1, Y \rightarrow x_2\}$
- A *semantic statement* is a pair  $(\langle s \rangle, E)$  where  $\langle s \rangle$  is a statement
- $ST$  is a stack of semantic statements

# Computations (abstract machine)

- A computation defines how the execution state is transformed step by step from the initial state to the final state
- The *execution state* is a pair  
 $(ST, \sigma)$
- $ST$  is a stack of semantic statements
- A *computation* is a sequence of execution states  
 $(ST_0, \sigma_0) \rightarrow (ST_1, \sigma_1) \rightarrow (ST_2, \sigma_2) \rightarrow \dots$

# Semantics

- To execute a program (i.e., a statement)  $\langle s \rangle$  the initial execution state is  
 $( [ \langle s \rangle , \emptyset ] , \emptyset )$
- $ST$  has a single semantic statement  $(\langle s \rangle , \emptyset)$
- The environment  $E$  is empty, and the store  $\sigma$  is empty
- $[ \dots ]$  denotes the stack
- At each step the first element of  $ST$  is popped and execution proceeds according to the form of the element
- The final execution state (if any) is a state in which  $ST$  is empty

skip

- The semantic statement is  
(skip,  $E$ )
- Continue to next execution step

# skip

- The semantic statement is  
 $(\text{skip}, E)$
- Continue to next execution step

# Sequential composition

- The semantic statement is  $(\langle s_1 \rangle \langle s_2 \rangle, E)$
- Push  $(\langle s_2 \rangle, E)$  and then push  $(\langle s_1 \rangle, E)$  on  $ST$
- Continue to next execution step

# Calculating with environments

- $E$  is mapping from identifiers to entities (both store variables and values) in the store
- The notation  $E(\langle y \rangle)$  retrieves the entity  $x$  associated with the identifier  $\langle y \rangle$  from the store
- The notation  $E + \{ \langle y \rangle_1 \rightarrow x_1, \langle y \rangle_2 \rightarrow x_2, \dots, \langle y \rangle_n \rightarrow x_n \}$ 
  - denotes a new environment  $E'$  constructed from  $E$  by adding the mappings  
 $\{ \langle y \rangle_1 \rightarrow x_1, \langle y \rangle_2 \rightarrow x_2, \dots, \langle y \rangle_n \rightarrow x_n \}$
  - $E'(\langle z \rangle)$  is  $x_k$  if  $\langle z \rangle$  is equal to  $\langle y \rangle_k$ , otherwise  $E'(\langle z \rangle)$  is equal to  $E(\langle z \rangle)$
- The notation  $E|_{\{ \langle y \rangle_1, \langle y \rangle_2, \dots, \langle y \rangle_n \}}$  denotes the projection of  $E$  onto the set  $\{ \langle y \rangle_1, \langle y \rangle_2, \dots, \langle y \rangle_n \}$ , i.e.,  $E$  restricted to the members of the set

# Calculating with environments (2)

- $E = \{X \rightarrow 1, Y \rightarrow [2\ 3], Z \rightarrow x_i\}$
- $E' = E + \{X \rightarrow 2\}$
- $E'(X) = 2,$   
 $E(X) = 1$
- $E|_{\{X,Y\}}$  restricts  $E$  to the 'domain'  $\{X,Y\}$ ,  
i.e., it is equal to  $\{X \rightarrow 1, Y \rightarrow [2\ 3]\}$

# Calculating with environments (3)

- `local X in`  
    `X = 1`                    (*E*)  
    `local X in`  
        `X = 2`                (*E'*)  
        `{Browse X}`  
    `end`                        (*E*)  
    `{Browse X}`  
`end`

# Lexical scoping

- Free and bound identifier occurrences
- An identifier occurrence is *bound* with respect to a statement  $\langle s \rangle$  if it is in the scope of a declaration inside  $\langle s \rangle$
- A variable identifier is declared either by a ‘local’ statement, as a parameter of a procedure, or implicitly declared by a case statement
- An identifier occurrence is *free* otherwise
- In a running program every identifier is bound (i.e., declared)

# Lexical scoping (2)

- `proc {P X}`  
  `local Y in Y = 1 {Browse Y} end`  
  `X = Y`  
`end`

# Lexical scoping (3)

- `local Arg1 Arg2 in`  
    `Arg1 = 111*111`  
    `Arg2 = 999*999`  
    `Res = Arg1*Arg2`  
`end`

Free Occurrences

Bound Occurrences

This is not a runnable program!

# Lexical scoping (4)

- `local Res in`
  - `local Arg1 Arg2 in`
    - `Arg1 = 111*111`
    - `Arg2 = 999*999`
    - `Res = Arg1*Arg2`
  - `end`
  - `{Browse Res}`
- `end`

# Lexical scoping (5)

```
local P Q in
  proc {P} {Q} end
  proc {Q} {Browse hello} end
  local Q in
    proc {Q} {Browse hi} end
    {P}
  end
end
end
```

# Exercises

42. Translate the following function to the kernel language:

```
fun {AddList L1 L2}
  case L1 of H1|T1 then
    case L2 of H2|T2 then
      H1+H2|{AddList T1 T2}
    end
  else nil end
end
```

43. Translate the following function call to the kernel language:

```
{Browse {Max 5 7}}
```

# Exercises

44. Explain the difference between static scoping and dynamic scoping. Give an example program that produces different results with static and dynamic scoping.
45. Think of a reason why static scoping may be preferable to dynamic scoping. Think of a reason why dynamic scoping may be preferable to static scoping.
