Announcements

- HW 1 is available on-line through the website (on the “Calendar”).
- Be sure to read through this information as you start implementation of HW1: “Misc Programming Information” (a link at the bottom of the left bar of the website).
- TA & instructor office hours are posted on website (“Weekly Schedule”).
- If you have not resolved issues with the C++ environment on your laptop, please do so immediately.
- If you cannot access the LMS site or the homework submission server, please email the instructor ASAP.
- Because many students were dealing with lengthy compiler/editor installation, registration confusion, etc., we will allow (for the first lab only!) students to get checked off for any remaining Lab 1 checkpoints at the beginning of next week’s Lab 2 or in your grad TA’s normal office hours.

Today

- Finish Lecture 1  
  - We left off around section 1.13.
  - Value Parameters & Reference Parameters
  - STL Strings
  - L-values vs. R-values
- STL Vectors as “smart arrays”

2.1 Character Arrays and String Literals

- In the line below "Hello!" is a string literal and it is also an array of characters (with no associated variable name).
  
  ```
  cout << "Hello!" << endl;
  ```
- A char array can be initialized as:  
  ```
  char h[] = {'H', 'e', 'l', 'l', 'o', '!', '\0'};
  ```
  or as:  
  ```
  char h[] = "Hello!";
  ```
  In either case, array h has 7 characters, the last one being the null character.
- The C and C++ languages have many functions for manipulating these “C-style strings”. We don’t study them much anymore because the standard string library is much more logical and easier to use.
- One place we do use them is in file names and command-line arguments, which you will use in Homework 1.

2.2 Conversion Between Standard Strings and C-Style String Literals

- We regularly convert/cast between C-style & C++-style (STL) strings. For example:
  ```
  string s1( "Hello!" );
  string s2( h );
  ```
  where h is as defined above.
- You can obtain the C-style string from a standard string using the member function `c_str`, as in `s1.c_str()`.

2.3 Standard Library (STL) Vectors

- Example Motivating Problem: Read an unknown number of grades and compute some basic statistics such as the mean (average), standard deviation, median (middle value), and mode (most frequently occurring value).
- Accomplishing this requires the use of vectors. Why can’t it be done (easily) with C-style arrays?
2.4 STL Vectors: “C++ Arrays”

- Standard library “container class” to hold sequences.
- A vector acts like a dynamically-sized, one-dimensional array.
- Capabilities:
  - Holds objects of any type
  - Starts empty unless otherwise specified
  - Any number of objects may be added to the end — there is no limit on size.
  - It can be treated like an ordinary array using the subscripting operator.
  - A vector knows how many elements it stores! (unlike C arrays)
  - There is NO automatic checking of subscript bounds.
- Here’s how we create an empty vector of integers:
  ```cpp
  vector<int> scores;
  ```
- Vectors are an example of a templated container class. The angle brackets `< >` are used to specify the type of object (the “template type”) that will be stored in the vector.
- `push_back` is a vector function to append a value to the end of the vector, increasing its size by one. This is an $O(1)$ operation (on average).
  - There is NO corresponding `push_front` operation for vectors.
- `size` is a function defined by the vector type (the vector class) that returns the number of items stored in the vector.
- After vectors are initialized and filled in, they may be treated just like arrays.
  - In the line
    ```cpp
    sum += scores[i];
    ```
    `scores[i]` is an “r-value”, accessing the value stored at location $i$ of the vector.
  - We could also write statements like
    ```cpp
    scores[4] = 100;
    ```
    to change a score. Here `scores[4]` is an “l-value”, providing the means of storing 100 at location 4 of the vector.
  - It is the job of the programmer to ensure that any subscript value $i$ that is used is legal — at least 0 and strictly less than `scores.size()`.

2.5 Initializing a Vector — The Use of Constructors

Here are several different ways to initialize a vector:

- This “constructs” an empty vector of integers. Values must be placed in the vector using `push_back`.
  ```cpp
  vector<int> a;
  ```
- This constructs a vector of 100 doubles, each entry storing the value 3.14. New entries can be created using `push_back`, but these will create entries 100, 101, 102, etc.
  ```cpp
  int n = 100;
  vector<double> b( 100, 3.14 );
  ```
- This constructs a vector of 10,000 ints, but provides no initial values for these integers. Again, new entries can be created for the vector using `push_back`. These will create entries 10000, 10001, etc.
  ```cpp
  vector<int> c( n*n );
  ```
- This constructs a vector that is an exact copy of vector `b`.
  ```cpp
  vector<double> d( b );
  ```
- This is a compiler error because no constructor exists to create an int vector from a double vector. These are different types.
  ```cpp
  vector<int> e( b );
  ```
2.6 Exercises

1. After the above code constructing the three vectors, what will be output by the following statement?
   
   ```cpp
   cout << a.size() << endl << b.size() << endl << c.size() << endl;
   ```

2. Write code to construct a vector containing 100 doubles, each having the value 55.5.

3. Write code to construct a vector containing 1000 doubles, containing the values 0, 1, √2, √3, √4, √5, etc. Write it two ways, one that uses `push_back` and one that does not use `push_back`.

2.7 Example: Using Vectors to Compute Standard Deviation

*Definition:* If \(a_0, a_1, a_2, \ldots, a_{n-1}\) is a sequence of \(n\) values, and \(\mu\) is the average of these values, then the standard deviation is

\[
\sqrt{\frac{\sum_{i=0}^{n-1} (a_i - \mu)^2}{n-1}}
\]

// Compute the average and standard deviation of an input set of grades.
#include <fstream>
#include <iomanip>
#include <iostream>
#include <vector> // to access the STL vector class
#include <cmath> // to use standard math library and sqrt

int main(int argc, char* argv[]) {
    if (argc != 2) {
        std::cerr << "Usage: " << argv[0] << " grades-file\n";
        return 1;
    }
    std::ifstream grades_str(argv[1]);
    if (!grades_str.good()) {
        std::cerr << "Can not open the grades file " << argv[1] << "\n";
        return 1;
    }
    std::vector<int> scores; // Vector to hold the input scores; initially empty.
    int x; // Input variable
    // Read the scores, appending each to the end of the vector
    while (grades_str >> x) { scores.push_back(x); }
    // Quit with an error message if too few scores.
    if (scores.size() == 0) {
        std::cout << "No scores entered. Please try again!" << std::endl;
        return 1; // program exits with error code = 1
    }
    // Compute and output the average value.
    int sum = 0;
    for (unsigned int i = 0; i < scores.size(); ++i) {
        sum += scores[i];
    }
    double average = double(sum) / scores.size();
    std::cout << "The average of " << scores.size() << " grades is "
              << std::setprecision(3) << average << std::endl;

    // Exercise: compute and output the standard deviation.
    double sum_sq_diff = 0.0;
    for (unsigned int i=0; i<scores.size(); ++i) {
        double diff = scores[i] - average;
        sum_sq_diff += diff*diff;
    }
    double std_dev = sqrt(sum_sq_diff / (scores.size()-1));
    std::cout << "The standard deviation of " << scores.size()
              << " grades is " << std::setprecision(3) << std_dev << std::endl;
}

2.8 Standard Library Sort Function

- The standard library has a series of algorithms built to apply to container classes.
- The prototypes for these algorithms (actually the functions implementing these algorithms) are in header file `algorithm`.
- One of the most important of the algorithms is `sort`.
- It is accessed by providing the beginning and end of the container’s interval to sort.
- As an example, the following code reads, sorts and outputs a vector of doubles:

```cpp
double x;
std::vector<double> a;
while (std::cin >> x) a.push_back(x);
std::sort(a.begin(), a.end());
for (unsigned int i=0; i<a.size(); ++i)
    std::cout << a[i] << '
';
```

- `a.begin()` is an iterator referencing the first location in the vector, while `a.end()` is an iterator referencing one past the last location in the vector.
  - We will learn much more about iterators in the next few weeks.
  - Every container has iterators: strings have `begin()` and `end()` iterators defined on them.
- The ordering of values by `std::sort` is least to greatest (technically, non-decreasing). We will see ways to change this.

2.9 Example: Computing the Median

The median value of a sequence is less than half of the values in the sequence, and greater than half of the values in the sequence. If \( a_0, a_1, a_2, \ldots, a_{n-1} \) is a sequence of \( n \) values AND if the sequence is sorted such that \( a_0 \leq a_1 \leq a_2 \leq \cdots \leq a_{n-1} \) then the median is

\[
\begin{cases} 
    a_{(n-1)/2} & \text{if } n \text{ is odd} \\
    \frac{a_{n/2-1} + a_{n/2}}{2} & \text{if } n \text{ is even} 
\end{cases}
\]

// Compute the median value of an input set of grades.
#include <algorithm>
#include <cmath>
#include <fstream>
#include <iomanip>
#include <iostream>
#include <vector>

void read_scores(std::vector<int> & scores, std::ifstream & grade_str) {
    int x; // input variable
    while (grade_str >> x) {
        scores.push_back(x);
    }
}

void compute_avg_and_std_dev(const std::vector<int>& s, double & avg, double & std_dev) {
    // Compute and output the average value.
    int sum=0;
    for (unsigned int i = 0; i < s.size(); ++i) {
        sum += s[i];
    }
    avg = double(sum) / s.size();
}
// Compute the standard deviation
double sum_sq = 0.0;
for (unsigned int i=0; i < s.size(); ++i) {
    sum_sq += (s[i]-avg) * (s[i]-avg);
}
std_dev = sqrt(sum_sq / (s.size()-1));
}

double compute_median(const std::vector<int> & scores) {
    // Create a copy of the vector
    std::vector<int> scores_to_sort(scores);
    // Sort the values in the vector. By default this is increasing order.
    std::sort(scores_to_sort.begin(), scores_to_sort.end());

    // Now, compute and output the median.
    unsigned int n = scores_to_sort.size();
    if (n%2 == 0) // even number of scores
        return double(scores_to_sort[n/2] + scores_to_sort[n/2-1]) / 2.0;
    else
        return double(scores_to_sort[n/2]); // same as (n-1)/2 because n is odd
}

int main(int argc, char* argv[]) {
    if (argc != 2) {
        std::cerr << "Usage: " "grades-file\n"
        return 1;
    }
    std::ifstream grades_str(argv[1]);
    if (!grades_str) {
        std::cerr << "Can not open the grades file " "\n"
        return 1;
    }
    std::vector<int> scores; // Vector to hold the input scores; initially empty.
    read_scores(scores, grades_str); // Read the scores, as before

    // Quit with an error message if too few scores.
    if (scores.size() == 0) {
        std::cout << "No scores entered. Please try again!" "\n"
        return 1;
    }

    // Compute the average, standard deviation and median
    double average, std_dev;
    compute_avg_and_std_dev(scores, average, std_dev);
    double median = compute_median(scores);

    // Output
    std::cout << "Among " "grades: " "average = " "std_dev = " "median = " "\n"
    << std::setprecision(3) << average << std::setprecision(3) << std_dev << std::setprecision(3) << median << std::endl;
    return 0;
}

2.10 Passing Vectors (and Strings) As Parameters

The following outlines rules for passing vectors as parameters. The same rules apply to passing strings.

- If you are passing a vector as a parameter to a function and you want to make a (permanent) change to the vector, then you should pass it by reference.
  - This is illustrated by the function read_scores in the program median_grade.
  - This is very different from the behavior of arrays as parameters.
• What if you don’t want to make changes to the vector or don’t want these changes to be permanent?
  – The answer we’ve learned so far is to pass by value.
  – The problem is that the entire vector is copied when this happens! Depending on the size of the vector, this can be a considerable waste of memory.

• The solution is to pass by **constant reference**: pass it by reference, but make it a constant so that it can not be changed.
  – This is illustrated by the functions `compute_avg_and_std_dev` and `compute_median` in the program `median_grade`.

• As a general rule, you should not pass a container object, such as a vector or a string, by value because of the cost of copying.
