# Lecture 10: A Taste of Number Theory

“Baba Yetu” performed by Ron Ragin & the Stanford  
Talisman, composed by Christopher Tin for *Civilization IV*

# Today's tasks

- Gentle reminder: Exam 2 on Wed. 2/26
- HW questions
- Divisibility & GCD
- Modular arithmetic
- Primes & cryptography

# But first: What is number theory?

- "Number theory is the queen of mathematics."  
--Carl Friedrich Gauss
- Number theory is the branch of pure math that is mostly concerned about integers and elements that can be constructed with them (e.g. rational numbers).
  - Basically, it's Discrete Math++
  - A lot of number theory is concerned with prime numbers.
  - One of the Millenium Prize Problems (the Riemann-Zeta Hypothesis) is intimately tied to the distribution of primes.

# Divisibility, quotients, & remainders

- As previously discussed,  $a$  is divisible by  $d$  means that there is some  $k \in \mathbb{Z}$  such that  $a = kd$ .
  - We often write  $d \mid a$ , read as " $d$  divides  $a$ ."
- What if  $d \nmid a$  (i.e.  $a$  is not divisible by  $d$ )?
  - Then  $a = kd + r$ , where  $r$  is the remainder.
  - With  $a$  and  $d$  fixed, how many integer solutions are there?
    - Infinite.
  - But what if we insist that  $0 \leq r < d$ ?
    - There is exactly one solution!

# The Quotient-Remainder Theorem

- Given  $a \in \mathbb{Z}$  and  $d \in \mathbb{N}$ , then there is exactly one pair of integers  $(k, r)$  that satisfies  $a = kd + r$  and  $0 \leq r < d$ .
- Put another way: When you divide an integer by a positive integer, there is one quotient and one remainder. Just like in grade school.

# Quick divisibility facts

- $\forall d \in \mathbb{N}, d \mid 0$
- If  $d \mid n$  and  $e \mid n$ , then  $de \mid n$ .
- If  $d \mid m$  and  $m \mid n$ , then  $d \mid n$ .
- If  $d \mid n$  and  $d \mid m$ , then  $d \mid (m + n)$ .
- If  $d \mid (m + n)$  and  $d \mid m$ , then  $d \mid n$ .
- If  $d \mid n$ , then  $\forall k \in \mathbb{N}, kd \mid kn$ .

# Greatest common divisor

- What are the divisors of 30?
  - $\{1, 2, 3, 5, 6, 15, 30\}$
- What are the divisors of 42?
  - $\{1, 2, 3, 6, 7, 14, 21, 42\}$
- 6 is the largest number in both lists, so  $\text{gcd}(30, 42) = 6$ .
- How can we calculate this in general?

# GCD algorithms

- The obvious approach: Generate both of those lists. How long will that take?
  - If you check all of the numbers from 1 to  $n$ , is that  $O(n)$ ?
    - No, because we define runtime in terms of the length of the input. If it takes  $b$  bits to write  $n$ , then  $n \approx 2^b$ , which means we've got exponential runtime.
    - Even if you stop at  $\sqrt{n}$ , that's still exponential.
- We need another approach.

# A surprising fact

- If  $n \geq m$ , then  $\gcd(n, m) = \gcd(m, r)$ , where  $r$  is the remainder of  $n \div m$ .
  - Proof:  $n = km + r$  - by the Q-R theorem,  $r$  is unique.
  - Let  $D = \gcd(n, m)$  and  $d = \gcd(m, r)$ .
  - Since  $d \mid m$  and  $d \mid r$ ,  $d \mid n$  as well. But since  $D$  is the greatest common divisor of  $n$  and  $m$ ,  $d \leq D$ .
  - Observe that  $r = n - km$ . Since  $D \mid n$  and  $D \mid m$ , then  $D \mid r$  as well. But since  $d$  is the greatest common divisor of  $m$  and  $r$ ,  $D \leq d$ .
  - $d \leq D \wedge D \leq d \leftrightarrow d = D$  ■

# Euclid's GCD Algorithm

```
def gcd(n,m):      # assume  $n \geq m \geq 1$   
    if m == 1:  
        return 1  
    return gcd(m, n%m)
```

This algorithm is linear in the number of bits of the input.

# GCD facts

- When  $\gcd(m, n) = 1$ , we say that  $m$  and  $n$  are relatively prime.
- If  $\gcd(a, b) = 1$  and  $\gcd(a, c) = 1$ , then  $\gcd(a, bc) = 1$ .
- If  $d \mid mn$  and  $\gcd(d, m) = 1$ , then  $d \mid n$ .
- $\forall k \in \mathbb{N}, \gcd(km, kn) = k \cdot \gcd(m, n)$
- If  $d \mid m$  and  $d \mid n$ , then  $d \mid \gcd(m, n)$ .

# Modular arithmetic

# Calculations on a clock

- It's 9am. What time will it be 6 hours from now?
  - 3pm. So  $9 + 6 = 3$ ?
  - Yes! At least when we're working *mod* 12.
- The overall idea is that, when working *mod*  $d$ , the only integers that exist are  $0, 1, \dots, d - 1$ .
  - We'll say that  $a \equiv b \pmod{d} \leftrightarrow d \mid (a - b)$ .

# Modular arithmetic identities

- If  $a \equiv b \pmod{d}$  and  $r \equiv s \pmod{d}$ , then:
  - $ar \equiv bs \pmod{d}$
  - $a + r \equiv b + s \pmod{d}$
  - $\forall k \in \mathbb{N}, a^k \equiv b^k \pmod{d}$
- In other words, addition and multiplication work in modular equations just like regular ones.

# Silly math tricks

- What is the last digit of  $7^{2025}$ ?
  - Observe that  $7^2 = 49 \equiv -1 \pmod{10}$ .
  - Observe that  $2025 = 2 \times 1012 + 1$ .
  - Observe that  $7^{2025} = (7^2)^{1012} \cdot 7$ .
  - $(7^2)^{1012} \cdot 7 \pmod{10} \equiv (-1)^{1012} \cdot 7 \pmod{10} \equiv 1 \cdot 7 \pmod{10}$

# Modular division

- $15 \cdot 6 \equiv 13 \cdot 6 \pmod{12}$ 
  - But  $15 \not\equiv 13 \pmod{12}$ !
- $15 \cdot 6 \equiv 2 \cdot 6 \pmod{13}$ 
  - And  $15 \equiv 2 \pmod{13}$ .
- The rule is: If  $ac \equiv bc \pmod{d}$  and  $\gcd(c, d) = 1$ , then  $a \equiv b \pmod{d}$ .
  - If  $\gcd(c, d) \neq 1$ , we cannot draw a conclusion.
  - Note that if  $d$  is prime, division just works.

# Multiplicative inverses

- If  $3 \times n = 1$ , what is  $n$ ?
  - What if I insist that  $n \in \mathbb{N}$ ?
  - There's no such integer!
- But... what if we were working mod 7?
  - $3 \times 5 = 15 \equiv 1 \pmod{7}$
- Any time the modulus is prime, then every value will have a multiplicative inverse, and it is easy to find.

# Fermat's Little Theorem

- If  $p$  is prime, then  $\forall k, k^p \equiv k \pmod{p}$ .
  - Proof is sketched out in your textbook.
  - Immediate corollary: As long as  $k \not\equiv 0$ , then  $k^{p-1} \equiv 1 \pmod{p}$ , and the multiplicative inverse of  $k$  is  $k^{p-2}$ .
- But, if the modulus  $m$  is composite, then:
  - Not every number has a multiplicative inverse, and...
  - ... finding one depends on factoring  $m$ , which is a very time-consuming problem.

# RSA public-key cryptography

# Cryptography: General idea

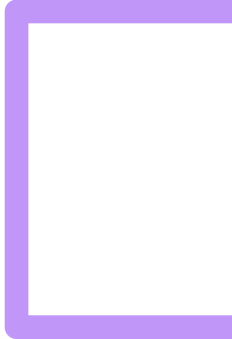

- Send a private message from A to B assuming that a third party E is eavesdropping on the transmission.
- The goal is to mathematically transform the message in a way that B can undo but E cannot.
- One approach is to agree upon a bitmask ahead of time – you just toggle a set of randomly chosen bits, and then no one can decode it without the bitmask/password.
  - But you have to agree ahead of time – inconvenient.

# Public key cryptography

- B publishes a “lock” that anyone can use to encrypt a message.
- B maintains the “key” to this lock, and keeps it secret from everyone.
- For this to work, the “locking” process needs to be difficult to reverse-engineer without the key.
- What might this “lock” and “key” mechanism look like?

# Key idea: The power of 1

- If you raise a value to the power of 1, what happens?
    - Right, nothing.
    - So what if you have two values that *multiply together to 1*?
    - And what if you use those values as *exponents*?
- 
- 

# RSA, briefly

- Since our plaintext message is just bits, we can represent it as a single number,  $p$ .
- B publishes an *encryption exponent*  $e$  and a modulus  $m$ . He keeps the *decryption exponent*  $d$  secret.
- To encrypt a message, A simply calculates the ciphertext as  $c = p^e \pmod{m}$ .
- To decrypt the message, B calculates  $c^d \equiv (p^e)^d \pmod{m}$ .
  - What does this tell you about  $e$  and  $d$ ?
  - $ed \equiv 1 \dots$  but not  $\pmod{m}$ !

# The right modulus

- If our modulus  $m$  were prime, then (per Fermat) it would be trivially easy for E to calculate  $d$  from  $e$  and  $m$ .
- If  $m$  has lots of small factors, then it is relatively easy to break it down to a manageable size quickly.
- The ideal case turns out to be where  $m = ab$ , where  $a$  and  $b$  are both LARGE prime numbers (with a few other conditions attached). This makes factoring  $m$  very challenging, and thus makes it very hard to figure out  $d$  from  $e$  and  $m$ .

# A toy example

- Let  $a = 11, b = 19$ . Then  $m = 209$ .
- In order for there to be an inverse, we need to select  $e$  to be relatively prime to  $(11 - 1)(19 - 1) = 180$ . Let's use 7.
- $d$  becomes the multiplicative inverse of 7 mod 180. This can be calculated quickly using a variant of Euclid's GCD algorithm. It turns out to be 179 here.
- So B publishes the public key (the "lock"):  $(209, 7)$

# A toy example

- $m = 209, e = 7$  (public)       $d = 179$  (secret)
- A wants to send the message: 50.
- They calculate  $50^7 \pmod{209} \equiv 107$ , and send 107 as the encrypted message.
  - If this is intercepted, there's isn't much E can do with it.
- B receives this and calculates  $107^{179} \pmod{209} \equiv 50$ .

# Important ideas we haven't discussed

- Why was our inverse mod 180 instead of mod 209?
  - More number theory. See: Euler's theorem and Euler's totient function.
- What is it about factoring that makes it hard, and how do we guarantee that?
  - Not sure, and we don't. We just don't have any polynomial-time (non-quantum) algorithms for doing so.
- How on Earth are we calculating numbers like  $107^{179}$ ?
  - Well,  $179 = 128 + 32 + 16 + 2 + 1...$

Questions?
