

TCP/IP

Transmission Control Protocol / Internet Protocol

Netprog: TCP/IP

1

TCP/IP & OSI

- In OSI reference model terminology - the TCP/IP protocol suite covers the *network* and *transport* layers.
- TCP/IP can be used on many data-link layers (can support many network hardware implementations).

Netprog: TCP/IP

2

But First ...

Netprog: TCP/IP

3

Ethernet - A Real Data-Link Layer

- It will be useful to discuss a real data-link layer.
- Ethernet (really IEEE 802.3) is widely used.
- Supported by a variety of physical layer implementations.

Netprog: TCP/IP

4

Ethernet

- Multi-access (shared medium).
- Every Ethernet interface has a unique 48 bit address (a.k.a. *hardware address*).
- Example: `c0:b3:44:17:21:17`
- The broadcast address is all 1's.
- Addresses are assigned to vendors by a central authority.

Netprog: TCP/IP

5

CSMA/CD

*Carrier Sense Multiple Access
with
Collision Detection*

- *Carrier Sense*: can tell when another host is transmitting
- *Multiple Access*: many hosts on 1 wire
- *Collision Detection*: can tell when another host transmits at the same time.

Netprog: TCP/IP

6

An Ethernet Frame

Preamble	Destination Address	Source Address	Len	DATA	CRC
8 bytes	6	6	2	0-1500	4

- The preamble is a sequence of alternating 1s and 0s used for synchronization.
- CRC is Cyclic Redundancy Check

Netprog: TCP/IP

7

Ethernet Addressing

- Each interface looks at every *frame* and inspects the destination address. If the address does not match the hardware address of the interface (or the broadcast address), the frame is discarded.
- Some interfaces can also be programmed to recognize *multicast* addresses.

Netprog: TCP/IP

8

Back to TCP/IP

Netprog: TCP/IP

9

Internet Protocol

The IP in TCP/IP

- IP is the network layer
 - packet delivery service (host-to-host).
 - translation between different data-link protocols.

Netprog: TCP/IP

10

An IP packet is called a *datagram*

IP Datagrams

- IP provides connectionless, unreliable delivery of *IP datagrams*.
 - Connectionless: each datagram is independent of all others.
 - Unreliable: there is no guarantee that datagrams are delivered correctly or even delivered at all.

Netprog: TCP/IP

11

IP Addresses

- IP addresses are not the same as the underlying data-link (MAC) addresses.

Why ?

Netprog: TCP/IP

12

IP Addresses

- IP is a network layer - it must be capable of providing communication between hosts on different kinds of networks (different data-link implementations).
- The address must include information about what *network* the receiving host is on. This is what makes routing feasible.

Netprog: TCP/IP

13

IP Addresses

- IP addresses are *logical* addresses (not physical)
- 32 bits. 
- Includes a network ID and a host ID.
- Every host must have a unique IP address.
- IP addresses are assigned by a central authority (*American Registry for Internet Numbers* for North America).

Netprog: TCP/IP

14

The *four* formats of IP Addresses

Class:

Netprog: TCP/IP

15

Class A

- 128 possible network IDs
- over 4 million host IDs per network ID

Class B

- 16K possible network IDs
- 64K host IDs per network ID

Class C

- over 2 million possible network IDs
- about 256 host IDs per network ID

16

Network and Host IDs

- A Network ID is assigned to an organization by a global authority.
- Host IDs are assigned locally by a system administrator.
- Both the Network ID and the Host ID are used for routing.

Netprog: TCP/IP

17

IP Addresses

- IP Addresses are usually shown in *dotted decimal* notation:

1.2.3.4 → 00000001 00000010 00000011 00000100

- cs.rpi.edu is 128.213.1.1

10000000 11010101 00000001 00000001

↖ CS has a class B network

Netprog: TCP/IP

18

Host and Network Addresses

- A single network interface is assigned a single IP address called the *host* address.
- A host may have multiple interfaces, and therefore multiple *host* addresses.
- Hosts that share a network all have the same IP *network* address (the network ID).

Netprog: TCP/IP

19

IP Broadcast and Network Addresses

- An IP broadcast address has a host ID of all 1s.
- IP broadcasting is not necessarily a true broadcast, it relies on the underlying hardware technology.
- An IP address that has a host ID of all 0s is called a *network address* and refers to an entire network.

Netprog: TCP/IP

20

Subnet Addresses

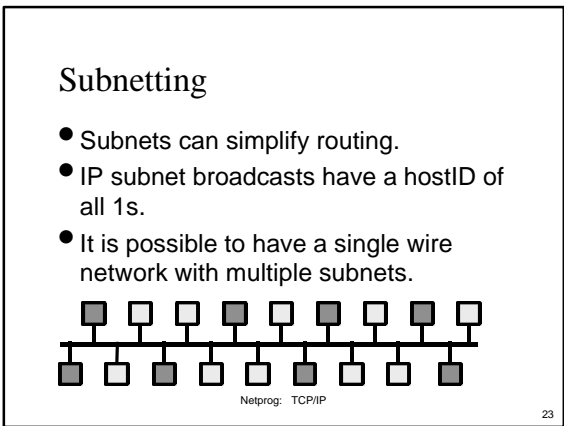

- An organization can subdivide its host address space into groups called subnets.
- The subnet ID is generally used to group hosts based on the physical network topology.

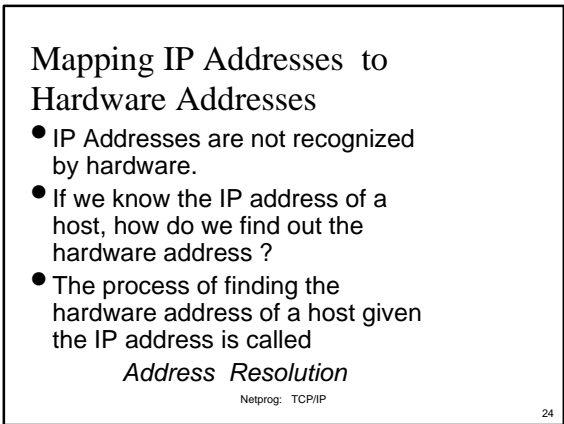

Netprog: TCP/IP

21

Reverse Address Resolution

- The process of finding out the IP address of a host given a hardware address is called
Reverse Address Resolution
- Reverse address resolution is needed by diskless workstations when booting (which used to be quite common).

Netprog: TCP/IP

25

ARP

Arp Arp!

- The *Address Resolution Protocol* is used by a sending host when it knows the IP address of the destination but needs the Ethernet (or whatever) address.
- ARP is a broadcast protocol - every host on the network receives the request.
- Each host checks the request against its IP address - the right one responds.

Netprog: TCP/IP

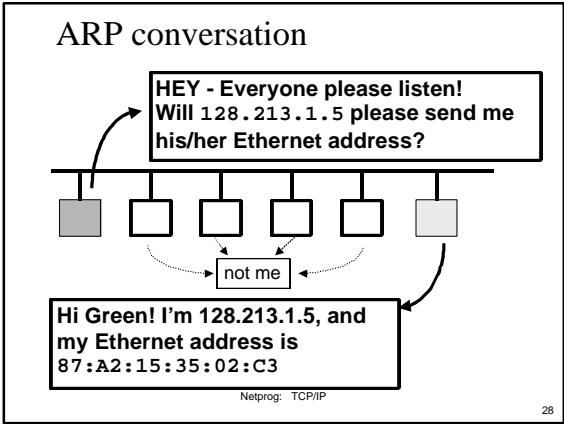

26

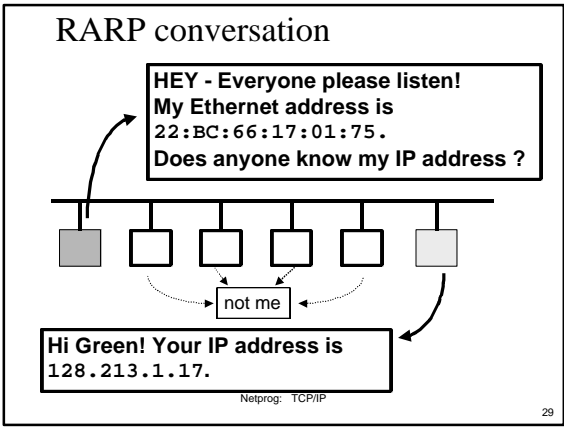

ARP (cont.)

- ARP does not need to be done every time an IP datagram is sent - hosts *remember* the hardware addresses of each other.
- Part of the ARP protocol specifies that the receiving host should also remember the IP and hardware addresses of the sending host.

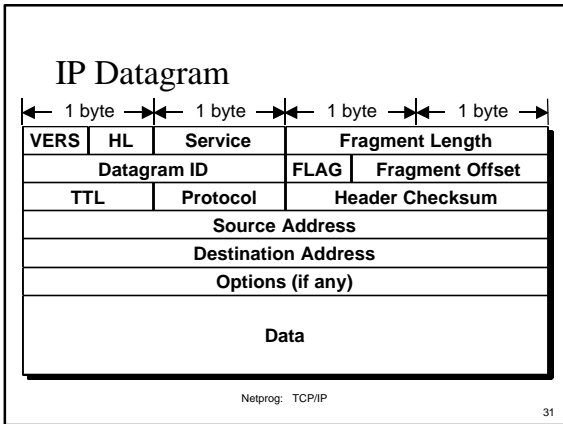

Netprog: TCP/IP

27

- ### Services provided by IP
- Connectionless Delivery (each datagram is treated individually).
 - Unreliable (delivery is not guaranteed).
 - Fragmentation / Reassembly (based on hardware MTU).
 - Routing.
 - Error detection.
- Netprog: TCP/IP 30

IP Datagram Fragmentation

- Each fragment (packet) has the same structure as the IP datagram.
- IP specifies that datagram reassembly is done only at the destination (not on a hop-by-hop basis).
- If any of the fragments are lost - the entire datagram is discarded (and an ICMP message is sent to the sender).

Netprog: TCP/IP 32

IP Flow Control & Error Detection

- If packets arrive too fast - the receiver discards excessive packets and sends an ICMP message to the sender (SOURCE QUENCH).
- If an error is found (header checksum problem) the packet is discarded and an ICMP message is sent to the sender.

Netprog: TCP/IP 33

ICMP

Internet Control Message Protocol

- ICMP is a protocol used for exchanging control messages.
- ICMP uses IP to deliver messages.
- ICMP messages are usually generated and processed by the IP software, not the user process.

Netprog: TCP/IP

34

ICMP Message Types

- Echo Request
- Echo Response
- Destination Unreachable
- Redirect
- Time Exceeded
- Redirect (route change)
- there are more ...

Netprog: TCP/IP

35

IP/BYE-BYE

- IP/BYE-BYE is a lecture protocol used to signal the class that we have just finished our discussion of IP - the network layer of TCP/IP.
- The appropriate response to an IP/BYE-BYE request is immediate applause, although simply opening your eyes is enough (known as a WAKEUP response).

Netprog: TCP/IP

36

Transport Layer & TCP/IP

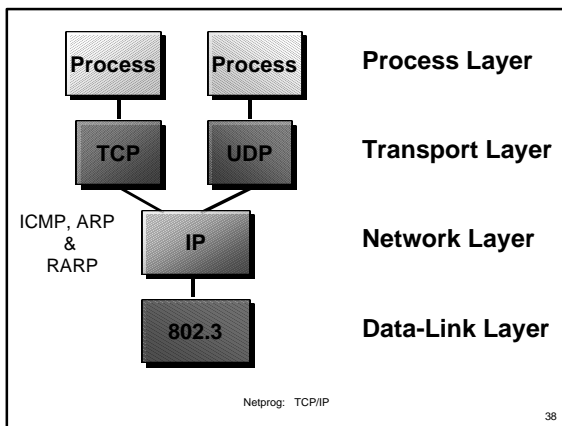

Q: We know that IP is the network layer - so TCP must be the transport layer, right ?

A: No... well, almost.

TCP is only part of the TCP/IP transport layer - the other part is UDP (User Datagram Protocol).

Netprog: TCP/IP

37

Netprog: TCP/IP

38

UDP User Datagram Protocol

- UDP is a transport protocol
 - communication between processes
- UDP uses IP to deliver datagrams to the right host.
- UDP uses *ports* to provide communication services to individual processes.

Netprog: TCP/IP

39

Ports spelled backwards is *strop* ...
Coincidence? (I think not!)

Ports

- TCP/IP uses an abstract destination point called a protocol port.
- Ports are identified by a positive integer.
- Operating systems provide some mechanism that processes use to specify a port.

Netprog: TCP/IP

40

Ports

Host A

Host B

Netprog: TCP/IP

41

UDP

The term *datagram* is also used to describe the unit of transfer of UDP!

- Datagram Delivery
- Connectionless
- Unreliable
- Minimal

UDP Datagram Format

Source Port	Destination Port
Length	Checksum
Data	

Netprog: TCP/IP

42

TCP

Transmission Control Protocol

- TCP is an alternative transport layer protocol supported by TCP/IP.
- TCP provides:
 - Connection-oriented
 - Reliable
 - Full-duplex
 - Byte-Stream

Wow!

Netprog: TCP/IP

43

Connection-Oriented

- *Connection oriented* means that a virtual connection is established before any user data is transferred.
- If the connection cannot be established - the user program is notified (finds out).
- If the connection is ever interrupted - the user program(s) is finds out there is a problem.

Netprog: TCP/IP

44

Reliable

Reliable does not mean that things don't go wrong, it means that we find out when things go wrong.

- *Reliable* means that every transmission of data is acknowledged by the receiver.
- If the sender does not receive acknowledgement within a specified amount of time, the sender retransmits the data.

Netprog: TCP/IP

45

Byte Stream

- *Stream* means that the connection is treated as a stream of bytes.
- The user application does not need to package data in individual datagrams (as with UDP).

Somebody needs to do this since IP is delivering all the data, it's just that the application layer doesn't need to do this!

Netprog: TCP/IP

46

Buffering

- TCP is responsible for buffering data and determining when it is time to send a datagram.
- It is possible for an application to tell TCP to send the data it has buffered without waiting for a buffer to fill up.

Netprog: TCP/IP

47

Full Duplex

- TCP provides transfer in both directions (over a single virtual connection).
- To the application program these appear as 2 unrelated data streams, although TCP can piggyback control and data communication by providing control information (such as an ACK) along with user data.

Netprog: TCP/IP

48

TCP Ports

- Interprocess communication via TCP is achieved with the use of ports (just like UDP).
- UDP ports have no relation to TCP ports (different name spaces).

Netprog: TCP/IP

49

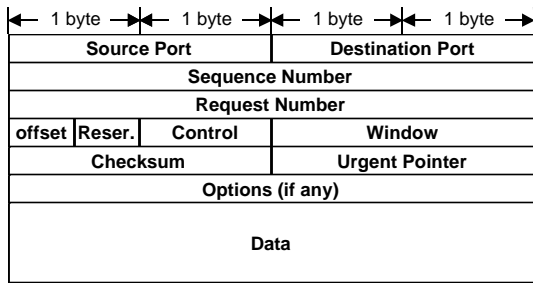

TCP Segments

- The chunk of data that TCP asks IP to deliver is called a *TCP segment*.
- Each segment contains:
 - data bytes from the byte stream
 - control information that identifies the data bytes

Netprog: TCP/IP

50

TCP Segment Format

51

Addressing in TCP/IP

- Each TCP/IP address includes:
 - Internet Address
 - Protocol (UDP or TCP)
 - Port Number

NOTE: TCP/IP is a *protocol suite* that includes IP, TCP and UDP.

Netprog: TCP/IP

52

TCP vs. UDP

Q: Which protocol is better ?

A: It depends on the application.

TCP provides a connection-oriented, reliable, byte stream service (lots of overhead).

UDP offers minimal datagram delivery service (as little overhead as possible).

Netprog: TCP/IP

53

TCP/IP Summary

- IP: network layer protocol
 - unreliable datagram delivery between hosts.
- UDP: transport layer protocol
 - unreliable datagram delivery between processes.
- TCP: transport layer protocol
 - reliable, byte-stream delivery between processes.

Netprog: TCP/IP

54

Hmmmmm. TCP or UDP ?

- Electronic commerce?
- Video server?
- File transfer?
- Email ?
- Chat groups?
- Robotic surgery controlled remotely over a network?

Netprog: TCP/IP
