

1 Planarity

A **curve** is the image of a continuous map from $[0, 1]$ to \mathbb{R}^2 . A **polygonal curve** is a curve composed of finitely many line segments. A **polygonal u, v -curve** starts at u and ends at v .

A **drawing** of a graph is a function f defined on $V(G) \cup E(G)$ that assigns each $v \in V(G)$ to a distinct point $f(v)$ in the plane and assigns each $e = (u, v) \in E(G)$ a polygonal $f(u), f(v)$ -curve. A point $x = f(e) \cap f(e')$ where $e \neq e'$ and x isn't a common endpoint of e and e' is called a **crossing**.

A graph is **planar** if it has a drawing without crossings. Such a drawing is a **planar embedding** of G . A **plane graph** is a particular planar embedding of a planar graph. The **faces** of a plane graph are the maximal regions of the plane that contain no point in the embedding. Every finite plane graph has one unbounded face, the **outer face**.

Let's show that K_5 and $K_{3,3}$ are not planar; i.e., we can't draw them such that no crossing exists.

A graph is **outerplanar** if it has an embedding with every vertex on the boundary of the unbounded face. The boundary of the outer face of a 2-connected outerplanar graph is a spanning cycle.

We can show that K_4 and $K_{2,3}$ are planar but not outerplanar.

2 Dual Graphs

The **dual graph** G^* of a plane graph G is a plane graph whose vertices are the faces of G . An edge $e^* = (x, y) \in G^*$ connects vertices x, y representing the faces X, Y separated by an edge $e \in E(G)$. The order in the plane of edges incident to $x \in V(G^*)$ is the order of the edges bounding the face of X in G in a walk around its boundary.

A dual graph can be dependent on a particular embedding of a planar graph. I.e., two embeddings of a planar graph can have dual graphs that are not isomorphic. However, whenever G is connected, it is possible for us to draw the dual such that G is isomorphic to $(G^*)^*$.

The **length** of a face of a plane graph G is the total length of the closed walks in G bounding the face. If $l(F_i)$ is the length of face F_i in plane graph G , then $2e(G) = \sum l(F_i)$.

If a plane graph G is bipartite, then every face of G has even length and the dual graph G^* is Eulerian.

3 Euler's Formula

Euler's Formula, $(n - e + f = 2)$, relates the number of vertices n with the number of edges e and faces f in a connected planar graph. We can easily prove that this relation holds. This implies that all planar embeddings of a connected graph G have the same number of faces.

If G is a simple plane graph with at least three vertices, then $e \leq 3n - 6$. If G is triangle-free, then $e \leq 2n - 4$. A **maximal planar graph** is a simple planar graph that is not a spanning subgraph of another planar graph. A **triangulation** is a simple plane graph where every face boundary is a 3-cycle. We can show that if G is a maximal planar graph, then G is a triangulation with $3n - 6$ edges.
