

Weighted edges: consider our edge set  $\rightarrow$  each edge has some associated weight

Graph  $G = (V, E, w)$

Minimum spanning tree: spanning tree on a <sup>edge-</sup>weighted graph that has the smallest possible sum of weights

- \*  $0-1-0$
- \*  $0-2-0$
- \*  $0-3-0$
- \*  $0-4-0$
- $0-5-0$

Prove: Kruskal outputs a M.S.T.

T: consider each edge we add

1.

] : Consider each edge we add

→ always joins two separate components

⇒ cut edge so doesn't introduce a cycle ✓

S : We assume  $G$  is connected

as we go until we're done

⇒ our  $T$  spans  $G$  ✓

M : pseudo-algorithmic argument

Consider that Kruskal outputs

some  $T$  s.t.  $T$  is not M.S.T.

where  $T^* = \text{M.S.T.}$

Consider some  $e \in E(T)$ ,  $e \notin E(T^*)$

where  $e$  is first such edge chosen

Consider adding  $e$  to  $T^*$  → creates cycle  $C$

Consider  $e' \in C$ ,  $e' \in E(T)$

Note:  $T^*$  has all edges in  $T$  that

were selected before  $e$

→ so  $e$  and  $e'$  were both available

→ so  $e$  and  $e'$  were both available for selection by  $T \Rightarrow w(e) \leq w(e')$

define  $T' = T^* + e - e'$

Note:  $W(T') \leq W(T^*)$   
Sum of weights

$\Rightarrow$  we have  $T'$  with more edges in common with  $T$  than  $T^*$

$\Rightarrow$  repeat the above argument

$T' \rightarrow$  converges to  $T \square$

Single-source shortest paths SSSP

→ from vertex  $u$ , identifying all shortest  $u, v$ -paths  $\forall v \in V(G)$

we care about distances  $d(u, v)$

as well as the paths themselves

→ Shortest paths tree

Note: not equal to M.S.T.

$$\bar{d}(u, v) = 6$$

$$d(u, v) = 5$$

Shortest paths tree

Example of SSSP via Dijkstra

	$D_0$	$D_1$	$D_2$	$D_3$	$D_4$	$D_5$
a	0	0	0	0	0	0
b	$\infty$	1	1	1	1	1
c	$\infty$	$\infty$	3	3	3	3
d	$\infty$	4	4	4		
e	$\infty$	$\infty$	$\infty$	$\infty$	exercise	
f	$\infty$	$\infty$	6	5		
					4 reader	

Show: correctness/optmality of Dijkstra

Prove: at each iteration

1 -  $\forall v \in X \quad D(v) = d(u, v)$   $\in$  actual shortest  $u, v$ -path length

2 -  $\forall v \notin X \quad D(v)$  is shortest  $u, v$ -path length from  $X$

$X$  = set of vertices visited during our algorithm

via weak induction on  $|X|$

$P(1) \Rightarrow X = \{u\} \quad D(u) = d(u, u) = 0$

$$P(1) \Rightarrow X = \{u\} \quad D(u) = d(u, u) = 0$$

all  $v \in N(u)$  take on distance of  $(u, v)$  edge

$$P(k) \Rightarrow |X| = k$$

assume v.a I.H. that the above holds

$$P(k+1) \Rightarrow X' = X + v$$

$v$  is selected s.t.  $D(v)$  is least of all  $v \notin X$

First show:  $D(v) = d(u, v)$

By I.H.  $\rightarrow$  shortest path directly from  $X$  to  $v$  is  $D(v)$ , so any other path that exits  $X$  and reaches  $v$  is bounded below by  $D(v)$   $\checkmark$

Secondly show:  $D(w)$  is "correct" for  $X' = X + v$   $\underbrace{w \notin X'}_{\text{weight of edge}}$

V.a I.H.  $\rightarrow D(w)$  is shortest  $u, w$  path distance directly from  $X$

$\dots (D(w) \dots)$  weight of edge

We update  $D(w) = \min(D(w), \underbrace{D(v)}_{\text{from } X} + \underbrace{W(w,v)}_{\text{weight of edge } (w,v)})$

→ shortest possible path <sup>from  $x_i$</sup>  directly through  $x'$ , as  $v$  is the only way to get to  $w$  through a vertex not originally in  $X$
