

# Judgment aggregation

acknowledgment: Ulle Endriss, University of Amsterdam

Lirong Xia

Rensselaer

Fall, 2016

# Last class: Fair division

- Indivisible goods
  - house allocation: serial dictatorship
  - housing market: Top trading cycles (TTC)

# Judgment aggregation: the doctrinal paradox

	Action p	Action q	Liable? ( $p \wedge q$ )
Judge 1	Y	Y	Y
Judge 2	Y	N	N
Judge 3	N	Y	N
<b>Majority</b>	<b>Y</b>	<b>Y</b>	<b>N</b>

- p: valid contract
- q: the contract has been breached
- Why paradoxical?
  - issue-by-issue aggregation leads to an illogical conclusion

# Formal framework

- An **agenda**  $A$  is a finite nonempty set of propositional logic formulas closed under complementation ( $[\varphi \in A] \Rightarrow [\sim\varphi \in A]$ )
  - $A = \{p, q, \sim p, \sim q, p \wedge q\}$
  - $A = \{p, \sim p, p \wedge q, \sim p \vee \sim q\}$
- A judgment set  $J$  on an agenda  $A$  is a subset of  $A$  (the formulas that an agent thinks is true, in other words, **accepts**).  $J$  is
  - **complete**, if for all  $\varphi \in A$ ,  $\varphi \in J$  or  $\sim\varphi \in J$
  - **consistent**, if  $J$  is satisfiable
  - $S(A)$  is the set of all complete and consistent judgment sets
- Each agent (judge) reports a judgment set
  - $D = (J_1, \dots, J_n)$  is called a profile
- An **judgment aggregation (JA) procedure**  $F$  is a function  $(S(A))^n \rightarrow \{0, 1\}^A$

# Some JA procedures

- Majority rule
  - $F(\varphi)=1$  if and only if the majority of agents accept  $\varphi$
- Quota rules
  - $F(\varphi)=1$  if and only if at least  $k\%$  of agents accept  $\varphi$
- Premise-based rules
  - apply majority rule on “premises”, and then use logic reasoning to decide the rest
- Conclusion-based rules
  - ignore the premises and use majority rule on “conclusions”
- Distance-based rules
  - choose a judgment set that minimizes distance to the profile

# Premise-based approaches

- $A = A_p + A_c$ 
  - $A_p$ =premises
  - $A_c$ =conclusions
- Use **the majority rule** on the premises, then use **logic inference** for the conclusions
- **Theorem.** If
  - the premises are all literals
  - the conclusions only use literals in the premises
  - the number of agents is odd
- then the premise-based approach is anonymous, consistent, and complete

	p	q	(p $\wedge$ q)
Judge 1	Y	Y	Y
Judge 2	Y	N	N
Judge 3	N	Y	N
<b>Majority</b>	<b>Y</b>	<b>Y</b>	<b>Logic reasoning Y</b>

# Recommender systems

The screenshot shows the Yelp interface for Shining Rainbow Restaurant. The header includes the Yelp logo, a search bar with the text "Find tacos, cheap dinner, Max's", and navigation links like "Home", "About Me", "Write a Review", "Find Friends", "Messages", and "Talk". The restaurant's name "Shining Rainbow Restaurant" is prominently displayed, along with its 4.2-star rating and 42 reviews. The address is 209 Central Ave, Albany, NY 12206. A map on the right shows the restaurant's location in Albany, NY, near Central Ave and University at Albany. Below the restaurant details, there are sections for "Review Highlights" and "Rating Distribution | Trend". The "Review Highlights" section shows three reviews: "Very good first visit, good food at a very reasonable price." (2 reviews), "I usually order pan-fried noodles with pork." (1 review), and "For the chinese, we had fried dumplings to start off." (8 reviews). The "Rating Distribution" shows a bar chart with 5 stars (red), 4 stars (orange), 3 stars (yellow), 2 stars (light green), and 1 star (dark green). The "People Who Viewed This Also Viewed..." section lists three other restaurants: Taiwan Noodle (70 reviews), Emperor's (21 reviews), and Ala Shanghai Chinese Cuisine (105 reviews). The "People Viewed This After Searching For..." section lists Rubble Tea Albany.

- Content-based approaches
  - based on user's past ratings on similar items computed using features
- Collaborative filtering
  - user-based: find similar users
  - item-based: find similar items (based on all users' ratings)

# Applications

# The Netflix challenge

- \$1M award to the first team who can outperform their own recommender system CinMatch by 10%
- A big dataset
  - half million users
  - 17000 movies
  - a secret test set
- Won by a hybrid approach in 2009
  - a few minutes later another hybrid approach also achieved the goal

# The problem

- Given
  - features of users  $i$
  - features of items  $j$
  - users' **ratings**  $r_i(j)$  over items
- Predict
  - a user's preference over items she has not tried
    - by e.g., predicting a user's rating of new item
- Not a social choice problem, but has a information/preference aggregation component

# Classical approaches

- Content-based approaches
- Collaborative filtering
  - user-based: find similar users
  - item-based: find similar items (based on all users' ratings)
- Hybrid approaches

# Framework for content-based approaches

- Inputs: profiles for items
  - $K$  features of item  $j$ 
    - $w_j = (w_{j1}, \dots, w_{jK})$
    - $w_{jk} \in [0, 1]$ : degree the item has the feature
  - the user's past ratings for items 1 through  $j-1$
- Similarity heuristics
  - compute the user's profile:  $v_i = (v_{i1}, \dots, v_{iK})$ ,  $v_{ik} \in [0, 1]$
  - recommend items based on the similarity of the user's profile and profiles of the items
- Probabilistic approaches
  - use machine learning techniques to predict user's preferences over new items

# Example

	Animation	Adventure	Family	Comedy	Disney	Bluesky	rate
	<b>1</b>	<b>1</b>	<b>1</b>	<b>0</b>	<b>0</b>	<b>1</b>	<b>?</b>
	<b>1</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>9</b>
	<b>1</b>	<b>0</b>	<b>1</b>	<b>1</b>	<b>1</b>	<b>0</b>	<b>8</b>
	<b>1</b>	<b>1</b>	<b>1</b>	<b>0</b>	<b>1</b>	<b>0</b>	<b>7</b>
<b><math>v =</math></b>	<b>0.8</b>	<b>0.8</b>	<b>0.75</b>	<b>0.85</b>	<b>0.75</b>	<b>0.9</b>	

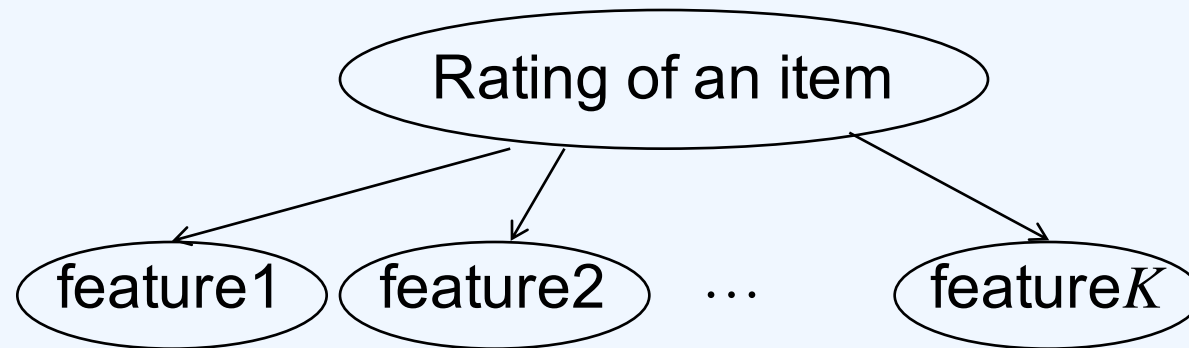

# Similarity heuristics

- A possible way to define  $v_i$ 
  - $v_{ik}$  is the average normalized score of the user over items with feature  $k$
- A possible way to define similarity measure
  - cosine similarity measure

$$\cos(v_i, w_j) = \frac{v_i \cdot w_j}{\|v_i\|_2 \|w_j\|_2} = \frac{\sum_{k=1}^K v_{ik} \cdot w_{jk}}{\sqrt{\sum_{k=1}^K v_{ik}^2} \sqrt{\sum_{k=1}^K w_{jk}^2}}$$

- in the previous example, the measure is 0.68

# Probabilistic classifier

- **Naïve Bayes model:** suppose we know
  - $\Pr(r)$
  - $\Pr(f_k|r)$  for every  $r$  and  $k$
  - learned from previous ratings using MLE
- Given  $w_j = (w_{j1}, \dots, w_{jK})$ 
  - $\Pr(r|w_j) \propto \Pr(w_j|r) \Pr(r) = \Pr(r) \prod \Pr(w_{jk}|r)$
  - Choose  $r$  that maximizes  $\Pr(r|w_j)$

# Framework for collaborative filtering approaches

- Inputs: a matrix  $M$ .
  - $M_{i,j}$ : user  $i$ 's rating for item  $j$

				
Alice	8	6	4	9
Bob	∅	8	10	10
Carol	4	4	8	∅
David	6	∅	10	5

- Collaborative filters
  - User-based: use similar **users**' rating to predict
  - Item-based: use similar **items**' rating to predict

# User-based approaches (1)

- Step 1. Define a similarity measure between users based on co-rated items
  - Pearson correlation coefficient between  $i$  and  $i^*$
  - $G_{i,i^*}$ : the set of all items that both  $i$  and  $i^*$  have rated
  - $\overline{M}_i$ : the average rate of user  $i$

$$\text{sim}(i, i^*) = \frac{\sum_{j \in G_{i, i^*}} (M_{ij} - \overline{M}_i) \cdot (M_{i^*j} - \overline{M}_{i^*})}{\sqrt{\sum_{j \in G_{i, i^*}} (M_{ij} - \overline{M}_i)^2} \sqrt{\sum_{j \in G_{i, i^*}} (M_{i^*j} - \overline{M}_{i^*})^2}}$$

# User-based approaches (2)

- Step 2. Find all users  $i^*$  within a given threshold
  - let  $N_i$  denote all such users
  - let  $N_i^j$  denote the subset of  $N_i$  who have rated item  $j$

# User-based approaches (3)

- Step 3. Predict  $i$ 's rating on  $j$  by aggregating similar users' rating on  $j$

$$\hat{r}_i(j) = \frac{1}{|N_i^j|} \sum_{i^* \in N_i^j} r_{i^*}(j)$$

$$\hat{r}_i(j) = \frac{\sum_{i^* \in N_i^j} \text{sim}(i, i^*) r_{i^*}(j)}{\sum_{i^* \in N_i^j} \text{sim}(i, i^*)}$$

$$\hat{r}_i(j) = \overline{M}_i + \frac{\sum_{i^* \in N_i^j} \text{sim}(i, i^*) (r_{i^*}(j) - \overline{M}_{i^*})}{\sum_{i^* \in N_i^j} \text{sim}(i, i^*)}$$

# Item-based approaches

- Transpose the matrix  $M$
- Perform a user-based approach on  $M^T$

# Hybrid approaches

- Combining recommenders
  - e.g. content-based + user-based + item-based
  - social choice!
- Considering features when computing similarity measures
- Adding features to probabilistic models

# Challenges

- New user
- New item
- Knowledge acquisition
  - discussion paper: preference elicitation
- Computation: challenging when the number of features and the number of users are extremely large
  - $M$  is usually very sparse
  - dimension reduction
