^{*} Concurrent Programming in Erlang, by J. Armstrong, R. Virding, C. Wikström, M. Williams

Overview of programming distributed systems

- It is harder than concurrent programming!
- Yet unavoidable in today's information-oriented society, e.g.:
 - Internet, mobile devices
 - Web services
 - Cloud computing
- Communicating processes with independent address spaces
- Limited network performance
 - Orders of magnitude difference between WAN, LAN, and intra-machine communication.
- Localized heterogeneous resources, e.g, I/O, specialized devices.
- Partial failures, e.g. hardware failures, network disconnection
- Openness: creates security, naming, composability issues.

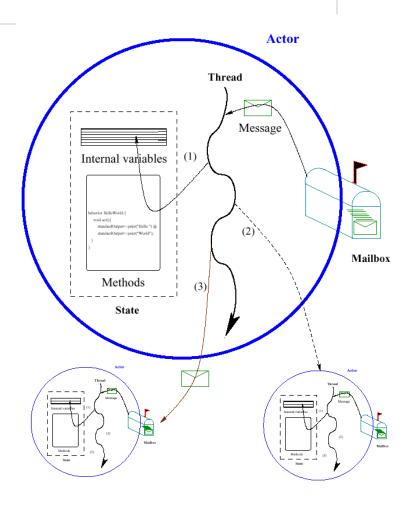

SALSA Revisited

SALSA

- Simple Actor Language System and Architecture
- An actor-oriented language for mobile and internet computing
- Programming abstractions for internet-based concurrency, distribution, mobility, and coordination
- C. Varela and G. Agha, "Programming dynamically reconfigurable open systems with SALSA", *ACM SIGPLAN Notices, OOPSLA 2001 Intriguing Technology Track,* 36(12), pp 20-34.

Advantages for distributed computing

- Actors encapsulate state and concurrency:
 - Actors can run in different machines.
 - Actors can change location dynamically.
- Communication is asynchronous:
 - Fits real world distributed systems.
- Actors can fail independently.

World-Wide Computer (WWC)

- Distributed computing platform.
- Provides a run-time system for *universal actors*.
- Includes naming service implementations.
- Remote message sending protocol.
- Support for universal actor migration.

Abstractions for Worldwide Computing

- *Universal Actors*, a new abstraction provided to guarantee unique actor names across the Internet.
- *Theaters*, extended Java virtual machines to provide execution environment and network services to universal actors:
 - Access to local resources.
 - Remote message sending.
 - Migration.
- *Naming service*, to register and locate universal actors, transparently updated upon universal actor creation, migration, garbage collection.

Universal Actor Names (UAN)

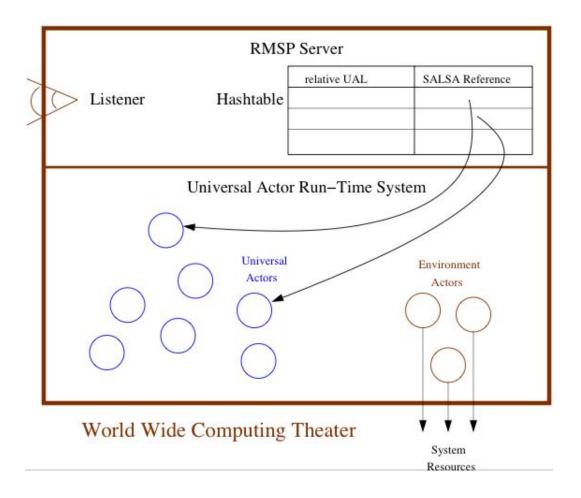

- Consists of human readable names.
- Provides location transparency to actors.
- Name to locator mapping updated as actors migrate.
- UAN servers provide mapping between names and locators.
 - Example Universal Actor Name:

```
Name server Unique address and (optional) port.

uan://wwc.cs.rpi.edu:3030/cvarela/calendar

Unique relative
actor name.
```

WWC Theaters

Universal Actor Locators (UAL)

- Theaters provide an execution environment for universal actors.
- Provide a layer beneath actors for message passing and migration.
- When an actor migrates, its UAN remains the same, while its UAL changes to refer to the new theater.
- Example Universal Actor Locator:

```
Theater's IP address and (optional) port.
```

SALSA Language Support for Worldwide Computing

- SALSA provides linguistic abstractions for:
 - Universal naming (UAN & UAL).
 - Remote actor creation.
 - Location-transparent message sending.
 - Migration.
 - Coordination.
- SALSA-compiled code closely tied to WWC run-time platform.

Universal Actor Creation

• To create an actor locally

```
TravelAgent a = new TravelAgent();
```

• To create an actor with a specified UAN and UAL:

```
TravelAgent a = new TravelAgent() at (uan, ual);
```

• To create an actor with a specified UAN at current location:

```
TravelAgent a = new TravelAgent() at (uan);
```

Message Sending

```
TravelAgent a = new TravelAgent();
a <- book( flight );</pre>
```

Message sending syntax is the same (<-), independently of actor's location.

Remote Message Sending

• Obtain a remote actor reference by name.

```
TravelAgent a = (TravelAgent)
  TravelAgent.getReferenceByName("uan://myhost/ta");
a <- printItinerary();</pre>
```

Reference Cell Service Example

```
module dcell;
behavior Cell implements ActorService{
   Object content;
   Cell(Object initialContent) {
         content = initialContent;
   }
   Object get() {
         standardOutput <- println ("Returning: "+content);</pre>
         return content;
   }
   void set(Object newContent) {
         standardOutput <- println ("Setting: "+newContent);</pre>
         content = newContent;
```

implements ActorService signals that actors with this behavior are not to be garbage collected.

Reference Cell Tester

Reference Cell Client Example

Address Book Service

```
module addressbook;
import java.util.*
behavior AddressBook implements ActorService {
   Hashtable name2email;
   AddressBook() {
         name2email = new HashTable();
   String getName(String email) { ... }
   String getEmail(String name) { ... }
   boolean addUser(String name, String email) { ... }
   void act( String[] args ) {
      if (args.length != 0) {
         standardOutput<-println("Usage: salsa -Duan=<UAN> -Dual=<UAL>
                                          addressbook.AddressBook");
```

Address Book Add User Example

Address Book Get Email Example

```
module addressbook;
behavior GetEmail {
    void act( String[] args ) {
      if (args.length != 2) {
           standardOutput <- println("Usage: salsa</pre>
             addressbook.GetEmail <AddressBookUAN> <Name>");
           return;
       getEmail(args(0),args(1));
    }
    void getEmail(String uan, String name){
              AddressBook book = (AddressBook)
                     AddressBook.getReferenceByName(new UAN(uan));
              standardOutput <- print(name + "'s email: ") @</pre>
              book <- getEmail(name) @</pre>
              standardOutput <- println(token);</pre>
           } catch (MalformedUANException e) {
              standardError<-println(e);</pre>
```

Erlang Language Support for Distributed Computing

- Erlang provides linguistic abstractions for:
 - Registered processes (actors).
 - Remote process (actor) creation.
 - Remote message sending.
 - Process (actor) groups.
 - Error detection.
- Erlang-compiled code closely tied to Erlang *node* run-time platform.

Erlang Nodes

To return our own node name:

```
node()
```

• To return a list of other known node names:

```
nodes()
```

• To monitor a node:

If flag is true, monitoring starts. If false, monitoring stops. When a monitored node fails, {nodedown, Node} is sent to monitoring process.

```
monitor_node(Node, Flag)
```

Actor Creation

• To create an actor locally

travel is the module name, agent is the function name, Agent is the actor name.

```
Agent = spawn(travel, agent, []);
```

• To create an actor in a specified remote node:

```
Agent = spawn(host, travel, agent, []);
```

host is the node name.

Actor Registration

• To register an actor:

ta is the registered name (an atom),
Agent is the actor name (PID).

```
register(ta, Agent)
```

• To return the actor identified with a registered name:

```
whereis(ta)
```

• To remove the association between an atom and an actor:

```
unregister(ta)
```

Message Sending

```
Agent = spawn(travel, agent, []),
    register(ta, Agent)

Agent ! {book, Flight}

ta ! {book, Flight}
```

Message sending syntax is the same (!) with actor name (Agent) or registered name (ta).

Remote Message Sending

• To send a message to a remote registered actor:

```
{ta, host} ! {book, Flight}
```

Reference Cell Service Example

Reference Cell Tester

Reference Cell Client Example

Address Book Service

```
-module (addressbook).
-export([start/0,addressbook/1]).
start() ->
    register(addressbook, spawn(addressbook, addressbook, [[]])).
addressbook(Data) ->
  receive
    {From, {addUser, Name, Email}} ->
       From ! {addressbook, ok},
       addressbook(add(Name, Email, Data));
    {From, {getName, Email}} ->
       From ! {addressbook, getname(Email, Data)},
       addressbook(Data);
    {From, {getEmail, Name}} ->
       From ! {addressbook, getemail(Name, Data)},
       addressbook (Data)
  end.
add(Name, Email, Data) -> ...
getname(Email, Data) -> ...
getemail(Name, Data) -> ...
```

Address Book Client Example

```
-module(addressbook client).
-export([getEmail/1,getName/1,addUser/2]).
addressbook server() -> 'addressbook@127.0.0.1'.
getEmail(Name) -> call addressbook({getEmail, Name}).
getName(Email) -> call addressbook({getName, Email}).
addUser(Name, Email) -> call addressbook({addUser, Name, Email}).
call addressbook (Msg) ->
   AddressBookServer = addressbook server(),
   monitor node (AddressBookServer, true),
    {addressbook, AddressBookServer} ! {self(), Msg},
    receive
       {addressbook, Reply} ->
           monitor node (AddressBookServer, false),
           Reply;
       {nodedown, AddressBookServer} ->
           no
    end.
```

Exercises

- 51. How would you implement the join block linguistic abstraction considering different potential distributions of its participating actors?
- 52. CTM Exercise 11.11.3 (page 746). Implement the example using SALSA/WWC and Erlang.
- 53. PDCS Exercise 9.6.3 (page 203).
- 54. PDCS Exercise 9.6.9 (page 204).
- 55. PDCS Exercise 9.6.12 (page 204).
- 56. Write the same distributed programs in Erlang.
