

The end of an era:

- Slota's box of 100 green tea bags in his office is no more
- Purchased circa 2017-18
- Expired September 2019 (still tasted fine this week)

Flow Networks

how much "flow" on each edge

$\forall e \in E(G)$: we have a capacity defined as $c(e) \geq 0$ (integer)

$[S, T]$ = our cut
 $|[S, T]| = 2$
 cut OR flow

a flow on G assigns to each edge e some flow value $f(e)$

→ This flow must be feasible

Feasible: $\forall e \in E(G): 0 \leq f(e) \leq c(e)$
 $\forall v \in V(G): f^-(v) = \text{sum of flows into } v$

$f^+(v) = \text{sum of flows out of } v$

Conservation of flow

$$\rightarrow f^-(v) = f^+(v)$$

$$f^+(s) = f^-(t)$$

↑
flows from source

↑
flows into sink

Give feasible flow f :

we define f -augmenting path P_f

- P_f goes from s to t

- $\forall e \in E(P_f)$:

if P_f follows a forward edge,
we need $f(e) < c(e)$

- if P_f follows a backward edge

if P_f follow a backward edge,
we need $f(e) > 0$

$\epsilon(e) = c(e) - f(e)$ as our tolerance
for forward edges

$\epsilon(e) = f(e)$ as our tolerance
for backward edges

Given P_f , we consider the
minimum tolerance over
all $e \in E(P_f)$

→ define as $z = \min_{e \in E(P_f)} \epsilon(e)$

To augment our flow:

$\forall e \in E(P_f): f(e) += z$ for forward e
 $f(e) -= z$ for backward e

Source-sink cut

$[S, T]$

$S =$ source set of vertices

S = source set of vertices

T = sink set of vertices

Note: the size of $|[S, T]|$ is just the sum of capacities of the cut edges

Q: How do we know which vertices are in S, T

A: $S = \{ \text{vertices that can be reached via } \underline{\text{pseudo-}s\text{-aug. paths}} \}$

$T = \bar{S} = \{ V(G) - S \}$

↗
maximal path from s but can't reach t and follows s -aug. path "rules"

Note: the size of any cut gives us a bound on maximum flow

$$|[S, T]| \geq \text{val}(f)$$

↑
total flow on u -network

total flow on
the network

Big Question

Does minimum cut = maximum flow

A: yes

↳ Let's prove this via a few relations/equivalences

1. f is a maximum flow
2. no s -aug. paths on our network
3. $|[S, T]| = \text{val}(f)$

We'll show $1 \Rightarrow 2 \Rightarrow 3 \Rightarrow 1$

(1 \Rightarrow 2)

contrapositive

(1 \Rightarrow 2) **Contrapositive**

$$\neg 2 \Rightarrow \neg 1$$

there exists an f -aug. path

$\Rightarrow f$ is not maximum

\rightarrow we've already shown how to increase flow using an f -aug path

(2 \Rightarrow 3)

no f -aug. paths $\Rightarrow |[S, T]| = \text{val}(f)$

Note: $s \in S, t \notin S$

all edges from $S \rightarrow T$ have

$$c(e) = f(e)$$

all edges from $T \rightarrow S$ have

$$f(e) = 0$$

$$\text{val}(f) = \sum \text{flows from } S \rightarrow T$$

$$- \underbrace{\sum \text{flows from } T \rightarrow S}$$

$$= 0$$

$$\text{val}(f) = \sum \text{flows from } S \rightarrow T$$

$$\begin{aligned} \text{val}(f) &= \sum \text{flows from } S \rightarrow T \\ &= \sum_{e \in [S, T]} c(e) = |[S, T]| \end{aligned}$$

(3 \Rightarrow 1) (cut = flow) \Rightarrow flow is maximum

Note: the capacities on edges gives us cut = flow

Q: Can we increase our flow?

A: No. Forward edges are at full capacity and backward edges are at zero flow

\Rightarrow we cannot increase our flow

Combined with with our earlier inequality

$\rightarrow \left\{ \begin{array}{l} \text{cut} \geq \text{max flow} \\ \text{and cut} = \text{max flow} \end{array} \right.$

\rightarrow minimum cut = maximum flow

□

To get max-flow/min-cut
(min s, t -cut)

Initialize all $f(e) = 0$

while \exists some f -aug. path P_f :

Find $z = \min$ tolerance on P_f

update $f(e)$ for all $e \in E(P_f)$

→ we're done

To get our min cut:

define our cut as $[S, T]$

$S =$ vertices reachable from s
on pseudo- f -aug. paths

$T =$ all other vertices

Basic Algorithm:

Ford-Fulkerson Algo

If we use BFS to find P_f :

Edmonds-Karp Algo

Example

$$S = \{s, 1, 2, 3, 5\}$$

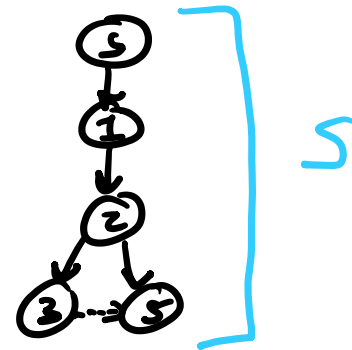

$$T = \{4, t\}$$

$\min \text{ cut} = 3$

$\min \text{ cut} = 1$

$$\text{val}(S) = 4$$

$$|[S, T]| = 4$$

max flow = 4 = min cut

WP7

Assume our G is undirected

→ to make G directed

replace each $e = (u, v) \in E(G)$
↳ with $e' = (u \rightarrow v)$
 $e'' = (v \rightarrow u)$

For the transformation:

* replace each vertex v with a single directed edge with unit capacity

* this edge can be specified via new vertices $v_0 \rightarrow v_1$, where v_0 has all of v 's in-edges, and v_1 has all of v 's out edges

* all other edges have infinite capacity

Note: we can define any arbitrary vertices in same G as our source/sink pair

Note: To prove $K(x,y) = A(x,y)$, think of the equivalence

(f -aug paths \leftrightarrow idps)

between our original G and transformed G'
